William James Morton * New York City; Harvard University Medical School, 1872; aged 74; a pioneer in electrotherapeutics; the son of Dr. William T. G. Morton of ether fame; for nearly thirty years professor of nervous and mental diseases and of electrotherapeutics in the New York Post-Graduate Medical School and Hospital; for five years professor of diseases of the mind and nervous system in the University of Vermont, Burlington; president of the American Electro-Therapeutic Association in 1893; physician to the Department of Nervous Diseases of the Metropolitan Throat Hospital, New York City; neurologist to the Randall's Island Hospitals and the New York Infant Asylum; editor and proprietor of the *Journal of Nervous and Mental Diseases*, from 1879 to 1885; died, March 26, in Miami, Fla., from heart disease.

John D. Blake * Baltimore; College of Physicians and Surgeons, Baltimore, 1875; aged 66; vice-president of the Medical and Chirurgical Faculty of Maryland, in 1893-1894; professor of clinical and operative surgery in Baltimore Medical College; surgeon to the Maryland General and St. Agnes hospitals, Baltimore; formerly health commissioner of Baltimore; died, March 30, from heart disease.

Edgar C. Loehr, Noblesville, Ind.; Medical College of Ohio, Cincinnati, 1871; aged 69; a member of the Indiana State Medical Association; local surgeon for the Pennsylvania and Big Four systems and Union Traction Company; for two terms mayor of Noblesville; died in the Noblesville Hospital, March 29, from cerebral hemorrhage.

John Dillon Thompson, Captain, M. C., U. S. Army; St. Louis College of Physicians and Surgeons, 1897; aged 44; a member of the Washington State Medical Association; on duty at Marfa, Tex.; while on leave of absence was found dead in a hotel in Phoenix, Ariz., April 4, supposedly from an overdose of chloroform.

John Alexander Black, Cleveland; Western Reserve University, Cleveland, 1913; aged 39; a member of the Ohio State Medical Association; Lieutenant, M. R. C., U. S. Army, and discharged December 26, 1918; formerly instructor in chemistry in the University of Chicago, and in his alma mater; died March 10.

Charles H. Wagner, Minneapolis; Homeopathic Hospital College, Cleveland, 1873; aged 67; vice-president and director of the Northwestern States Portland Cement Company, Mason City, Iowa; the Trinity Portland Cement Company, Dallas, and the Northwestern Metal Ware Company, Minneapolis; died March 1.

Alexander Peter Reid, L'Ardoise, N. S.; McGill University, Montreal, 1858; L. R. C. S., Edinburgh, 1858; University of the City of New York, 1865; aged 83; formerly emeritus professor of medicine and examiner in medical jurisprudence and hygiene in Dalhousie University, Halifax, N. S.; died February 27.

Lane Mullally * Charleston, S. C.; Medical College of the State of South Carolina, Charleston, 1889; aged 53; vice dean and professor of obstetrics in his alma mater; a member of the Southern Surgical and Gynecological Association; local surgeon of the Southern Railway; died, March 25.

Elmer Melville Whitney, New Bedford, Mass.; Jefferson Medical College, 1879; aged 64; a member of the Massachusetts Medical Society and New England Ophthalmological Society; ophthalmic surgeon to St. Luke's and St. Mary's hospitals, New Bedford; died, February 27.

Thomas Stanley Crowe, Chicago; Illinois Medical College, Chicago, 1896; aged 51; a member of the Illinois State Medical Society; once physician of Cook County; Captain, M. R. C., U. S. Army, and discharged March 29, 1919; also a pharmacist; died, April 5, from cholelithiasis.

Edward Young Napier, Waverly, Tenn.; Vanderbilt University, Nashville, Tenn., 1880; University of Nashville, Tenn., 1882; aged 76; county health officer of Humphreys County and division surgeon for the Nashville-Chattanooga and St. Louis Railroad; died March 10.

Carl Augustus Meyer * Newman Grove, Neb.; University of Nebraska, Omaha, 1915; aged 30; secretary-treasurer of the Madison County Medical Society; Captain, M. R. C., U. S. Army, and discharged Sept. 12, 1919; died, February 13, from pneumonia following influenza.

Fred W. Upson * Conneaut, Ohio; Western Reserve University, Cleveland, 1882; aged 61; medical supervisor of the New York, Chicago and St. Louis, New York Central, and Bessemer and Lake Erie railroads; died, March 18, from intestinal obstruction.

Crispin Wright, Fruitland, Ida.; Denver and Gross College of Medicine, Denver, 1910; aged 37; Lieut., M. C., National Army; who served with the American Expeditionary Forces in France; died in U. S. General Hospital No. 19, Oteen, N. C., February 22.

John R. Hereford, Jr. * Major, M. C., U. S. Army, retired; Ferguson, Mo.; St. Louis Medical College, 1883; aged 58; Major and Surgeon, Thirty-Second Infantry, U. S. V., with service in the Philippine Islands; died, March 27, from cerebral hemorrhage.

Jerome Gil Atkinson, New York City; University of the City of New York, 1876; aged 76; acting assistant surgeon, U. S. Army; medical director of the Banker's Life Insurance Company of New York City; died, March 22, from influenza.

Robert Elbert Yarbrough, Harrisburg, Ark.; University of Louisville, Ky., 1910; aged 36; health officer of Poinsett County; died in the Paragould, Ark., Sanitarium, March 20, from septicemia following an infected wound of the finger.

Frederick Charles Thompson, East Tawas, Mich.; University of Michigan, Ann Arbor, 1887; aged 53; a member of the Michigan State Medical Society; died at the home of his nephew in Mt. Clemens, Mich., March 15, from uremia.

Augustus Homer Brown * Bayside, N. Y.; College of Physicians and Surgeons in the City of New York, 1894; aged 56; for twenty years one of the police surgeons of New York City; died, April 2, from heart disease.

Helene Siverine Lassen, Brooklyn; New York Medical College and Hospital for women, Homeopathic, New York City, 1871; one of the organizers of the Memorial Dispensary for Women and Children; died, March 25.

Francis Elmer Bingham, New York City; University and Bellevue Hospital Medical College, New York City, 1913; aged 31; first lieutenant, M. C., U. S. Army, and honorably discharged, Dec. 21, 1918; died, March 25.

George W. Thompson, New York City; Eclectic Medical College of the City of New York, 1885; aged 65; professor of theory and practice of medicine and clinical medicine in his alma mater; died April 3.

Stephen Joseph Johnson, Lowell, Mass.; University of the City of New York, 1877; for two years a member of the board of aldermen, and for six years a member of the Lowell school committee; died, March 21.

John Lindahl * La Jolla, Calif.; Drake University, Des Moines, Iowa, 1888; aged 55; formerly medical director of the Swedish National Sanatorium for Tuberculosis, Denver; died, March 19.

Henry Eastwood Bickford * Memphis, Tenn.; (license, Tennessee, 1915); aged 35; in charge of the Red Cross Emergency Hospital in Memphis during the influenza epidemic; died March 21.

Alexander D. Farnsworth, Arkansas City, Kan.; University Medical College of Kansas City, Mo., 1898; aged 46; was instantly killed, January 31, by the overturning of his automobile.

Wellington R. Harring, Philadelphia; Temple University, Philadelphia, 1909; aged 42; a member of the Medical Society of the State of Pennsylvania; died, April 1, from a general breakdown.

James Miller McCreedy * Sewickley, Pa.; Bellevue Hospital Medical College, 1887; aged 59; died at the home of his cousin in Baltimore, March 18, from cerebral hemorrhage.

Frank Fletcher, Jenkins Bridge, Va.; Jefferson Medical College, 1869; aged 74; a member of the Medical Society of Virginia; died, February 25, from cerebral hemorrhage.

Thomas H. Wilson, Dennison, Ohio; Starling Medical College, Columbus, Ohio, 1869; aged 75; a member of the city council of Pittsburgh in 1896-1897; died, March 22.

Talbot Reed, Atlantic City, N. J.; University of Pennsylvania, Philadelphia, 1894; for two terms health officer of Atlantic City; died, March 19, from nephritis.

William Benjamin Harrison, Columbia, Tenn.; University of Louisville, Ky., 1856; aged 89; a member of the Tennessee State Medical Association; died February 5.

John R. Reeve, DeLand, Fla.; formerly of Superior, Wis.; University of Toronto, Ont., 1857; a member of the Florida Medical Association; died about March 22.

Brooks DeForest Norwood, Westport, Conn.; New York Homeopathic Medical College and Flower Hospital, New York City, 1912; aged 42; died, March 20.

John H. Young, New Cumberland, Pa.; Homeopathic Hospital College, Cleveland, 1874; aged 83; a veteran of the Civil War; also a clergyman; died March 23.

Abraham H. Faith * Denver; Medical College of Indiana, Indianapolis, 1886; St. Louis College of Physicians and Surgeons, 1892; aged 61; died February 21.

Louis Francis Keever * Parkersburg, W. Va.; St. Louis College of Physicians and Surgeons, 1913; aged 61; died, February 16, from pernicious anemia.

Parke Custis Sickler * Wilkes-Barre, Pa.; Baltimore Medical College, 1900; aged 47; died in the Philadelphia Hospital, March 6, from angina pectoris.

W. E. Swinney, McRae, Ga.; Medical College of Georgia, Augusta, 1869; aged 73; for several years city clerk of McRae; died, March 10, from nephritis.

James H. Giles, Big Sandy, Tenn.; University of Tennessee, Nashville, 1892; aged 55; died, March 18, from double pneumonia following influenza.

Alexander R. McDonald, Boyd, Wis.; McGill University, Montreal, 1882; aged 68; died in Minneapolis, March 13, from arteriosclerosis.

Alvin Marion Lakin * Yale, Ia.; Rush Medical College, 1884; aged 62; died in the Methodist Hospital, Des Moines, Ia., January 19.

William L. Bullis, Allerton, Ia.; Philadelphia University of Medicine and Surgery, 1870; aged 74; died, recently, from heart disease.

Charles E. Blacker, Indianapolis; Medical College of Ohio, Cincinnati, 1880; aged 78; died, March 23, from heart disease.

Charles S. Briggs, Nashville, Tenn.; University of Nashville, 1875; died in the Briggs Infirmary, Nashville, March 23.

William Vernon Van Norman, Los Angeles; Cleveland Homeopathic Medical College, 1898; aged 44; died March 28.

George Washington Wilson, Vaiden, Miss.; Medical College of Alabama, Mobile, 1894; aged 60; died March 23.

Samuel F. Nash * Bessemer, Ala.; Birmingham, Ala., Medical College, 1908; aged 42; died in February.

Andrew Lincoln Belt * Fort Dodge, Ia.; State University of Iowa, Iowa City, 1890; aged 58; died March 7.

Frank Fletcher Carr, Holden, Mass.; Harvard University Medical School, 1893; aged 50; died March 6.

Clarence Fletcher Swift, Harlan, Ind.; University of Michigan, Ann Arbor, 1877; died about March 10.

Edgar Leonard Walker, Moriah, N. Y.; University of Vermont, Burlington, 1883; died March 23.

D. W. Faulkner, Foxboro, Ont.; McGill University, Montreal, 1878; aged 67; died March 4.

Marriages

HOWARD DAVIS LEWIS, Baltimore, to Mrs. Flora M. Gottschall of Sunbury, Pa., March 25.

ALICE MITCHELL DE FOREST to Mr. John Wilfred Drummond, both of Detroit, April 2.

SAMUEL J. MCNEILL, Chicago, to Miss Edna E. Hamilton of Toronto, Ont., March 31.

ROY LEE SMITH to Miss Hazel Elizabeth Miles, both of Indianapolis, April 6.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

SOME MISBRANDED NOSTRUMS

Mendenhall's No. 40 for the Blood.—The J. C. Mendenhall Medicine Co. of Evansville, Ind., shipped in March, 1917, some of its nostrum "Mendenhall's No. 40 for the Blood"

which was misbranded. Analyzed by the Bureau of Chemistry, the stuff was reported to consist essentially of potassium iodid, cathartic resins, ammonium acetate, licorice, glycerin, sugar, alcohol and water. It was falsely and fraudulently sold as a cure for syphilis, aneurysm of the aorta, gonorrhea, eczema, rheumatism, catarrh, malaria, and diseases of the liver, kidneys and spleen. In November, 1918, the company pleaded guilty and was fined \$100 and costs.—[Notice of Judgment No. 6637; issued March 22, 1920.]

MENDENHALL'S
Number 40
For the Blood
A Remedy of Great Power
For the cure of **SYPHILIS, RHEUMATISM, SCROFULA, MALARIA, CONSTIPATION, LIVER DISEASES, SORES, ULCERS and all SKIN ERUPTIONS**
Chronic Pulmonary Diseases, such as **BRONCHIAL CATARRH, CHRONIC COUGHS, ASTHMA and the PREVENTION OF CONSUMPTION.**
The result of 40 years' experience in the compounding of physicians' prescriptions. Prepared by J. C. Mendenhall, Pharmacist since 1875.
Price, \$1.00 BOTTLE
Six Bottles for \$5.00, sent to any part of the U. S. on receipt of price, charges prepaid.
J. C. Mendenhall Medicine Co.
SOLE OWNERS
EVANSVILLE, INDIANA, U. S. A.

Zaegel's Essence and Lung Balsam.—Max R. Zaegel, Sheboygan, Wis., who traded as M. R. Zaegel & Co., shipped in April, 1917, quantities of "Zaegel's Essence" and "Zaegel's Lung Balsam." The government chemists analyzed the "Essence" and reported that it consisted essentially of alcohol, water, sugar and plant extractives, including a laxative substance and a saponin. The "Lung Balsam" was also analyzed and reported to consist essentially of alcohol, water, sugar and laxative plant material flavored with oil of peppermint. The "Essence" was falsely and fraudulently represented as a cure for rheumatism, stomach, liver, bowel and kidney complaints, headaches, diseases of women and ner-

vousness, as well as a remedy for heart trouble and a preventive of appendicitis. The "Lung Balsam" was falsely and fraudulently represented as a cure for coughs, lung and throat troubles and whooping cough and effective, when used in connection with "Z. M. O.," as a cure for pneumonia and when used with the "Essence" as a cure for consumption. In September, 1918, Zaegel pleaded guilty and was fined \$110.—[Notice of Judgment No. 6628; issued March 22, 1920.]

McGraw's Liquid Herbs of Youth.—George W. McGraw, who traded as the McGraw Remedy Co., Little Rock, Ark., shipped in December, 1916, a quantity of "McGraw's Liquid Herbs of Youth." The Bureau of Chemistry reported that this marvel was, essentially, Epsom salt, senna, red pepper, quassia, alcohol and water with wintergreen flavor.

McGraw's Liquid Herbs of Youth was represented as a cure for rheumatism, scald head, pimples, syphilis, ringworm, headache, pains in the back, catarrh, female weakness and some other conditions and it was claimed to invigorate the nervous system and impart new life and energy to all functions of the body at the same time that it was eradicating disease. These claims were declared false and fraudulent. McGraw pleaded guilty in September, 1918, and was fined \$10.—[Notice of Judgment No. 6673; issued March 29, 1920.]

Jarabe de Ambrozoïn.—The American Apothecaries Co., Astoria, N. Y., shipped during March, 1917, a quantity of "Jarabe de Ambrozoïn." The Bureau of Chemistry reported that analysis showed this product to be composed essentially of terpin hydrate, menthol, benzoic acid, ammonium chlorid, sodium bromid, glycerin, alcohol, sugar and water. It was falsely and fraudulently represented as a treatment for laryngitis, asthma, whooping cough and tuberculosis. In February, 1919, the company pleaded guilty and was fined \$100.—[Notice of Judgment No. 6642; issued March 22, 1920.]

Kampfmüller's Rheumatic Remedy.—The Kampfmüller Rheumatic Remedy Co., Louisville, Ky., shipped in December, 1916, a quantity of "Kampfmüller's Rheumatic Remedy." The Bureau of Chemistry reported that this consisted essentially of potassium iodid, plant extractives, alcohol and water. It was falsely and fraudulently represented as a cure for arthritic rheumatism, articular rheumatism, inflammatory rheumatism, muscular rheumatism and rheumatic fever. In October, 1918, the company pleaded guilty and was fined \$25.—[Notice of Judgment No. 6684; issued March 29, 1920.]

Sal-Sano.—Ernst Bischoff, New York City, who traded as the Sal-Sano Co., shipped in July, 1917, a quantity of Sal-Sano, which was misbranded. The Bureau of Chemistry reported that analysis showed this stuff to contain essentially:

Sodium chlorid (common salt)	19.9 per cent.
Sodium phosphate	13.6 per cent.
Sodium bicarbonate (baking soda)	42.2 per cent.
Sodium sulphate (Glauber's salt)	20 per cent.

This mixture was falsely and fraudulently represented as a cure for diabetes "when in truth and in fact it was not."

305 N. 3rd St., Philadelphia, Pa.

Diabetes

Treated with greatest success without restricted diet. Physio-nutritive Sal-Sano removes all symptoms of the disease, produces gain in weight, muscle and nerve power and energy. At leading druggists. Write for booklet.

SAL-SANO COMPANY
114 WEST BROADWAY. NEW YORK

In December, 1918, Bischoff pleaded guilty and was fined \$100.—[Notice of Judgment No. 6658; issued March 29, 1920.]

Indian Wyanoke.—Albert M. Follett, who did business as Park & Russell Co., Concord, N. H., shipped a quantity of Indian Wyanoke in May, 1917, which was misbranded. Analysis by the Bureau of Chemistry showed the product to consist essentially of chloroform, ammonia, menthol, glycerin, turpentine-like oils, alcohol and water. The stuff was falsely and fraudulently represented as a remedy for diphtheria,

consumption, pleurisy, pneumonia, deafness, sore eyes, rheumatism, "creeping paralysis," felons, peritonitis, appendicitis, baldness, dandruff and many other things. In April, 1919, Follett pleaded guilty and was fined \$25 and costs.—[Notice of Judgment No. 6664; issued March 29, 1920.]

Gregory's Antiseptic Oil.—"Gregory's Antiseptic Oil" was a nostrum shipped by the C. J. Lincoln Co., Little Rock, Ark., in August, 1917. The Bureau of Chemistry reported that analysis showed the preparation to consist approximately of 89 per cent. kerosene oil with small amounts of oil of cloves, cassia and sassafras with a trace of camphor and pepper resins. The preparation was falsely and fraudulently represented as a cure for rheumatism, hog cholera, pneumonia, big-jaw, lung troubles, sweeny, asthma, bighead, coughs, blind staggers, pleurisy, blackleg, backache, sore throat, kidney troubles, consumption and one or two other things. The C. J. Lincoln Co. pleaded guilty in April, 1919, and was fined \$50.—[Notice of Judgment No. 6670; issued March 29, 1920.]

Correspondence

A STATEMENT CONCERNING THE RADIUM SITUATION

To the Editor:—Late in the year 1912 the Bureau of Mines undertook an investigation of the radium-bearing ores situated in Colorado and Utah. This investigation resulted in the publication in 1913 of a bulletin of the Bureau of Mines entitled "A Preliminary Report on Uranium, Radium and Vanadium," by Richard B. Moore and Karl L. Kithil. Up to the time this bulletin was published, the larger proportion of the ore mined had been shipped abroad, mainly to England, France and Germany, where the uranium, vanadium and radium were extracted. One company, however, in this country was greatly interested in the extraction of radium from carnotite, and at the time of publication of this bulletin had made a good start toward the desired end.

Very few people, however, in the United States knew anything concerning these deposits, and a still fewer number had any definite idea that they might be used as a commercial source of radium. Even a large proportion of the miners had only a hazy idea concerning the fact that the ore contained radium, as the European buyers emphasized that they were purchasing the ore for the vanadium which it contained.

In 1912 no one had a real conception of the value of these deposits to the United States and to the world in general. Whereas a limited number of people knew that they contained radium and a certain number in this country were interested in the possible extraction of radium from these ores, the fact that they constituted the largest deposit of radium-bearing ore in the world was not known until the publication of Bulletin 70 of the Bureau of Mines, referred to above. On page 42 of this bulletin there appears:

The United States possesses unique deposits in these carnotite ores. They constitute at present the largest known supply of radium-bearing minerals in the world. With the exception of the ore mined and utilized by two firms, practically every pound is shipped abroad. Up to the present very little interest has been shown by Americans in these deposits, which may not be duplicated, so far as quantity goes, in any part of the world.

The only other large deposits of uranium-bearing ores are those in Austria. They are considered of such importance that the Austrian government has taken entire charge of them. The output from the carnotite fields of this country is much larger than that from the Austrian mines and is likely to continue larger for some time to come, but the ore should be mined with minimum waste and the industry should yield a maximum profit to this country.

Since 1913 the situation as regards the extraction and recovery of radium has changed, and at the present time this country produces much more radium than all the rest of the world put together.

On account of the fact that these are the largest radium deposits in the world, there has been a tendency to overestimate the amount of ore available and the probable length of time the deposits will be the source of commercial radium. There is naturally, under such circumstances, a difference of opinion as to the probable amount of ore that can be produced. No one can tell exactly just how much radium ore can be derived from these fields. To some extent the future production will depend on the price, as a much higher price would allow lower grade ore to be mined and treated. As the ore always exists in pockets of varied sizes and grades, the mining has been largely confined to outcrops, which has made the question of an estimation of the probable amount of ore available easier than if mining conditions were such as are encountered in connection with other metals. The larger proportion of these outcrops have now been worked out, and the more important companies have been and are drilling and mining small bodies of ore which have been located below the surface. It follows that as mining becomes more expensive and the grade of ore treated becomes lower, the price of radium must necessarily increase, unless very much more efficient methods of treatment are discovered than are used at the present time, and this is not likely.

Based on the present production and anything like the present price of radium, it is probable that the carnotite deposits of Colorado and Utah will not last as a commercial source of ore for longer than six to ten years. It is difficult to estimate the total amount of radium that has been produced in the world, but it is probably somewhere between 100 and 110 gm. of radium element. Of this amount about 70 gm. of radium have been produced in this country, and an appreciable quantity of the other 30 to 40 gm. extracted abroad have come from exported American ores. It can be readily seen, therefore, that nearly three quarters of the total world's production of radium has come from American carnotite ores.

Whereas more than 100 gm. of radium have actually been produced, there is not by any means 100 gm. available today. A considerable amount of both American and European radium has gone into the production of luminous paint for watches, clocks, electric light push buttons, etc. The amount of radium used for these purposes, however, is small in proportion to the war uses both here and abroad. The dials on the instruments used on practically all aeroplanes were marked with radium luminous paint. Radium was also used in the war for gunsights and various other purposes, and nearly the whole production of 1919 as well as a large proportion of the production of 1918 was used for war purposes in which the radium was permanently lost. Not only is this true, but as Germany, France and England were rather short on radium, especially the first nation, a considerable amount of radium abroad which previously had been used for cancer treatment was drawn on for war purposes. Even in this country a number of physicians sold their supplies. Owing to the varied uses for war purposes it is impossible to state just how much radium is left at present; but the amount is very considerably less than the 100 to 110 gm. actually produced.

Owing to these facts, to the limited life of the radium ore deposits, and to the successful use of radium in cancer work and for other therapeutic purposes, it is important that the physicians of this country should consider the matter very carefully and take such steps as are necessary to provide radium for the needs of cancer patients before the material is gone or has been used for other purposes.

In order that the radium plants may run and the extraction of radium may be possible, it is necessary to have a market for the product; and if there is not a sufficient demand for medical purposes, no one can blame the manu-

facturers for finding other uses. It therefore becomes necessary to find ways and means for purchasing the radium from the manufacturers while it is possible to do so.

This is partly being taken care of by private purchases for hospitals. It is difficult to estimate exactly how much radium is in use in this country at present for such purposes; but it is probably between 20 and 25 gm. Not only can the present and future situation be ameliorated by encouraging further purchases by individuals and hospitals, but great good might be accomplished by obtaining either from the government or from private sources funds to purchase a large amount of radium during the next five years which could be placed in the hands of some proper organization to be administered for the benefit of the people of the United States.

RICHARD B. MOORE, Washington, D. C.

Chief Chemist, U. S. Bureau of Mines.

"THE CAUSE OF ABSCESS OF THE LUNG AFTER TONSILLECTOMY"

To the Editor:—In THE JOURNAL, April 3, 1920, p. 941, Dr. Clendening states his suspicion that motor-driven ether apparatus may be a frequent cause of lung abscess after tonsillectomy. He goes farther and states that the use of these machines should be discontinued until their innocence is proved.

My work is that of an expert anesthetist, and in the course of a month I probably work with a dozen different operators for tonsillectomy, thus becoming familiar with many and varied types of technic. From my own experience it would seem to me altogether too radical to condemn the use of an apparatus found so valuable by so many men on the sole argument of "post hoc ergo propter hoc."

Dr. Clendening does not mention whether the position used during operation in his cases was the dorsal one or not, nor does he say whether those patients having lung abscess following tonsillectomy were returned to bed in the dorsal position and kept so during recovery of their reflexes; but I would presume that the dorsal position was used.

Now, if ether blower and suction apparatus is responsible for the complication of lung abscess after these operations, is it not more reasonable to say that the suction portion of the apparatus is responsible in that it has made thorough tonsillectomy possible in the dorsal position and has so delayed men in changing to some position in which the throat draining is by gravity forward into the mouth, such as the lateral position of the patient's body with mouth turned down or capable of being turned down when necessary? Is there any excuse for carrying a patient back to bed, flat on his back after a tonsillectomy, to "gargle" and inhale septic throat contents and blood, when he could just as easily be transported in the prone position with the head turned to one side and so let gravity keep the airways free?

I believe that these motor-driven machines are found too valuable by a large number of operators to condemn them until we have completely eliminated the old hazardous dorsal position during operation, and especially every second of the time after operation until the patient is conscious and the reflexes are intact.

RALPH M. WATERS, M.D.,

Sioux City, Iowa.

Use of "Patent Medicines" in Tuberculosis.—The extreme danger of depending in the least on "patent medicines" for the cure of tuberculosis is emphasized by the thousands of persons every year who have trusted to their false promises until so much time has been lost that their cases have become hopeless.—*Bull. Maine State Dept. of Health*, October, 1919.

AN INVESTIGATION OF CONDITIONS IN THE DEPARTMENTS OF THE PRECLINICAL SCIENCES

Report of a Committee of the Division of Medical Sciences of the National Research Council

JOSEPH ERLANGER, M.D., ST. LOUIS; C. M. JACKSON, M.D., MINNEAPOLIS; GRAHAM LUSK, NEW YORK; W. S. THAYER, M.D., BALTIMORE, AND V. C. VAUGHAN, M.D., ANN ARBOR, MICH.

RESOLUTIONS ADOPTED UNANIMOUSLY BY THE DIVISION OF MEDICAL SCIENCES

WHEREAS, A committee composed of Drs. Joseph Erlanger, C. M. Jackson, Graham Lusk, W. S. Thayer and V. C. Vaughan appointed by the Division of Medical Sciences of the National Research Council to study the situation in regard to the supply of assistants in preclinical departments has made a thorough study of this in the medical schools of the country and submitted a report setting forth existing conditions and analyzing suggestions as to improvement; and

WHEREAS, This study shows that there is a serious scarcity of men of proper caliber for assistants in preclinical sciences seeking such positions; be it

Resolved, By the Division of Medical Sciences of the National Research Council:

1. That this deficiency in assistants constitutes a very serious menace to medical education because not alone are there insufficient assistants for the present needs of instruction in the preclinical sciences, but the deficiency of the present inevitably must result in an inadequate number of men qualified for higher positions in the preclinical sciences, and a consequent deterioration in these departments in a very few years.

2. That since the clinical departments are in many ways dependent for their efficiency on the instruction afforded and the investigation conducted in the preclinical sciences, deterioration in the preclinical sciences will result in deterioration in the clinical departments.

3. That since these conditions enumerated under 1 and 2 exist, it is very essential that steps be taken to provide for a more satisfactory supply of assistants in the preclinical sciences.

4. That since directly or indirectly the remedy for these conditions depends to a large degree on increased budgets for salaries for assistants, instructors, assistant professors and professors, and for technicians and supplies, it is highly important that funds be secured for these purposes to prevent deterioration in the entire structure of medical education.

5. That, since this need for funds for the preclinical sciences seems so pressing, the larger proportion of funds available for developing medical education should be applied to the preclinical rather than to the clinical departments of the medical schools for the present and until such time as a more satisfactory situation is obtained in the preclinical sciences.

REPORT OF THE COMMITTEE

To the Division of Medical Sciences of the National Research Council:

Gentlemen:—Your committee appointed to consider the present paucity of satisfactory assistants in the departments of the preclinical sciences (anatomy, bacteriology, pathology, biochemistry, pharmacology, physiology, etc.) and its probable effect on investigation in the medical sciences and to advise the National Research Council through the Division of Medical Sciences of any plan that should be undertaken to correct this deficiency, beg leave to report as follows:

The data on which this report is based were gathered by means of a questionnaire addressed to the heads of the depart-

ments of the preclinical sciences in all Class A medical schools. When the information available was insufficient to permit of addressing it to the head of the department by name, the questionnaire was addressed to the department. Some of the letters must, therefore, have been addressed to nonexistent departments. And, inasmuch as two or even three subjects often are combined into one department, it must frequently have happened that one and the same individual received two or more copies of the questionnaire. It therefore is impossible to determine accurately the number of departments that have failed to reply. Two hundred and ninety-eight copies were distributed. We can be sure only that we have failed to hear from something over fourteen departments. The replies received up to the time this report was prepared (February 20) numbered 139. Copies of all, including thirty-one received since, accompany the report. An adequate conception of the problem can be obtained alone by reading the whole set.

Owing to the number and, in many instances, the length of the replies, it is impossible to publish all of them. This is to be regretted not alone because of their value as an exposition of the situation in medical education, but also because alone by publication in full is it possible to avoid running the risk of inadequately presenting the problem. An alternative, and the one we have been forced to adopt, is to publish a limited number of the replies. In order to avoid as far as possible the danger of making a selection on the basis of personal inclination, the arbitrary decision was made to select one reply from each of the twenty-six schools that had returned three or more answered questionnaires up to the time of preparing this report. The medical schools that fall into this category are: Leland Stanford Junior University; University of California; Yale University; Emory University; Northwestern University; Rush; University of Illinois; University of Iowa; Johns Hopkins University; Harvard University; University of Michigan; University of Minnesota; St. Louis University; University of Missouri; Washington University; University of Nebraska; Columbia University; Cornell University; University and Bellevue Hospital; University of Cincinnati; Western Reserve University; University of Pennsylvania; University of Pittsburgh; University of Texas; University of Virginia, and University of Wisconsin.

The considerations determining the selection of the reply from a given school have been, first, brevity, and second, representativeness. Occasionally a longer reply has been selected because of its more thoughtful treatment of the subject. In the case of two of the schools, a second reply (Nos. 27 and 28) has been transcribed because of their unusual point of view. The replies have been edited only to the extent of obscuring the identity of the writers and of eliminating irrelevant matter. The distribution of the selected replies among the several preclinical subjects happens to be as follows: anatomy, 6; biologic chemistry, 3; biologic chemistry and physiology, 1; pathology, 6; pathologic chemistry, 1; pharmacology, 2; physiology, 5; physiology and pharmacology, 1, and experimental medicine, 1.

QUESTIONS SUBMITTED

The questions the heads of the departments were requested to answer were as follows:

1. Is your department experiencing any difficulty in filling vacancies and in holding men? If so, to what cause or causes do you attribute the difficulty?

2. Do you succeed in obtaining as assistants the best qualified men from among those eligible? If not, what becomes of such men?

3. Can you suggest a plan or plans that might lead the best qualified men to take up your subject as a career?

4. Can you suggest a plan or plans for increasing the number of men from whom might be selected assistants for the preclinical departments?

In the replies published herewith, the marginal numbers indicate the number of the question that is being answered.

REPLIES ¹

1

1. Yes. I am in receipt of innumerable requests for men to fill both academic positions and hospital laboratory positions and have no one in sight for 90 per cent. of the requests. So far I have been unable to hold any of the men that I have trained. I am able to keep them until they are well trained and then they receive offers that they should not refuse. The cause is entirely financial. It is, perhaps, especially marked in pathology as compared to other fundamental branches, because a pathologist must have a clinical training and therefore is able to accept the much more attractive opportunities offered in clinical medicine than in pathology; also hospital laboratories are increasing in importance and many of them are offering much larger salaries than men of similar experience can possibly secure in universities. Furthermore, these hospital laboratory positions in many instances offer good facilities for research work.

2. Yes. We obtain usually some of the best, eligible men as assistants because medical students recognize that advanced training in pathology is the best stepping stone to further advance in clinical medicine, just as in former years anatomy was the high road for the ambitious surgeon.

3. In my judgment there is just one solution of the problem and that is that the rewards at the top of the ladder be adequate to compensate the beginner for his period of sacrifice to attain that goal. Young men are perfectly willing to sacrifice financial advantage for some time in medicine and law as well as other professions, because at the end is a goal that is worth the sacrifice. Formerly the advantages of academic life were sufficient to induce some of the best men, and especially those with the higher ideals of work and service, to forsake the road of financial success in clinical medicine to secure the advantages that the universities had to offer. Now that the professors in clinical branches are being given all the academic privileges with much higher possibilities of remuneration, this same type of men, from whom the faculty of pathology must be recruited, naturally forsakes pathology for the clinical branches. . . . Unless a radical change is made very quickly, in a very few years there will be no competent men in pathology. There will merely be a few men who have been in pathology too long to change and young men who are taking pathology with the expectation of shifting at the earliest possible moment to one of the clinical branches. The clinical branches in the past have recruited their teachers and research men almost entirely from the laboratories in the fundamental sciences. The recent exaltation of clinical branches is merely another case of slaughtering the goose that lays the golden egg. It will be perhaps easier to put the departments of pathology on the same footing as the clinical branches than the other fundamental branches, since the pathological laboratories play such an increasingly important part in the conduct of the clinical work. To recruit the pathological faculties it is necessary to place the department of pathology on the same footing in every respect as the department of internal medicine. When the opportunities in pathology and internal medicine are equal then equally good men will be available in each subject.

4. I believe that the answer to 3 covers Question 4. When physiology and pathology offer careers corresponding to those of the clinical branches, they will have plenty of assistants, but until then, their assistants will be not only deficient in number but especially inferior in quality.

1. On account of lack of space, only seven of the twenty-eight replies selected for publication appear in this article, one from each of seven of the better supported schools. Each represents a different preclinical subject. The complete paper containing the twenty-eight representative replies will be reprinted as a pamphlet and will be sent on receipt of stamped, directed envelop.

8

1. In the past this department has had difficulties in filling vacancies. The assistants in the department have almost invariably been candidates for the Ph.D. degree, i. e., they have been men of little experience in research, in teaching, and in general knowledge of physiology. Until this year we have had few men as assistants who have had the medical degree. The department here has also had difficulty in holding men. . . . The difficulty in filling vacancies and in holding men is in my opinion twofold. One is a financial difficulty, the other is more complex and will be considered in Section 3. First, with reference to the financial condition; the highest pay which we have been able to offer to assistants has been \$500 a year. . . . Furthermore, the higher places, such as instructorships, assistant professorships and the professorship, are inadequately compensated. In my opinion an instructor should not receive less than \$2,400 annually, and an assistant professor should receive \$3,600 or \$4,000.

Top salaries for professors in the preclinical subjects throughout the country are commonly regarded as appropriately lower than that given to full-time clinical men by half or at least by several thousand dollars. I have not seen any good reason for this arrangement except that which is based on the capability of the clinician to go outside, and by devoting his time to practice, to gain larger returns. This is a possibility which the laboratory man likewise had at one time. He should not be penalized because he has surrendered it in devotion to the advancement of medical knowledge. It seems to me that the object of having full-time clinical men, as it is in having full-time laboratory men, lies in the provision for research. If both types of investigators are conducting medical research, there is no reason either in the character of the research or in its results, which justifies the distinction that has been drawn. This distinction is likely to breed a feeling of injustice in medical faculties and possibly a restlessness due to unfair discrimination. If such an attitude does arise, it seems to me that there will be a tendency for the best men to seek clinical rather than laboratory chairs.

If there is anxiety lest the laboratory departments will not be manned by the best men, the danger of such a result should be provided against now.

2. With reference to securing the best qualified men, it may be stated at once that it is rare for such men to enter service here in the laboratory departments. They go into clinical work. This tendency has been especially marked since clinical research has become prominent. It is possible now for a person having an interest in physiology, for example, to obtain work in a first class hospital in which he can satisfy his physiological interest, use physiological methods, conduct physiological research, keep in touch with patients, have room, board and laundry supplied, and frequently a satisfactory salary in addition. The meager opportunities offered in the laboratories of the medical school as compared with those in the laboratories of a very good hospital are distinctly unfavorable to men pursuing careers in laboratory subjects.

3. With regard to plans for leading the best qualified men to take up preclinical subjects as a career I wish to suggest several considerations:

(a) Adequate financial return for beginners, as well as for persons who have gained experience, must be provided as indicated above.

(b) We are in a vicious circle by not being properly manned. If a department has a professor, an assistant professor and several instructors who are all well-trained, active investigators, they by contact with the students, are able to interest them in investigation and thus increase their chances of becoming permanently attached to investigation as a pursuit. Just because we have an inadequate or ill-qualified personnel we continue to have such a personnel.

(c) The most important means of interesting alert, keen-minded students in medical research is by contact with investigation. I believe that inquiry among our leading investigators would show that it was some chance oppor-

tunity of learning what research really is that led them to undertake it permanently. The rigidity of the medical curriculum and its complete filling of all available time result in a definite crowding out to the possibility of men undertaking special work, in any of the preclinical subjects, unless they have had some previous experience and can therefore be released from the ordinary routine. . . .

4. I believe that the plan suggested under 3 will serve to increase the number of men from whom assistants might be selected for work in preclinical departments. . . .

Besides considerations which are directed in the main towards inducing *medical* students to go permanently into preclinical branches, there should be considered the probability that we shall have to depend to a considerable extent on possessors of the Ph.D. degree for adequately trained candidates for research positions. . . . I believe that any preclinical department would do well to get into relation with the academic department of the university and count upon receiving a certain number of candidates for the Ph.D. degree as assistants. I believe that it would be a mistake in the development of medicine to have the whole department thus manned.

12

1. No more than should be expected. The chief factor is "clinical opportunities": at least what the prospective assistant believes to be clinical opportunities.

2. Yes.

3. Clinical subjects, of course, are more attractive to the vast number of men. But that this is true in the case of the very best men, I am not so sure. I would suggest that clinical subjects are in need of men of high ideals and that it is better that they be allowed to go in that direction.

4. This has always been an economic question. The salaries paid to clinical assistants are so great by comparison as to exclude all competition.

16

1. Yes. Lack of either immediate or future remuneration, commensurate with remuneration in other lines.

2. No. They go into the clinical branches.

3. Much larger salaries for present and future.

4. Much larger salaries.

19

1. None . . . since we have a fairly large department. One professor, three assistant professors, three instructors, and three assistants. The small, two and three men anatomical departments have great trouble in getting and holding their men; only the professor can survive the burden of routine work. Young men also seem more inclined to work in departments where there are several more advanced men working. We need more fully developed laboratory departments in the medical schools before we can hope to attract capable men, as they must see work being done.

2. We have trouble getting the best medical students to come in the laboratory as assistants. They go into medical practice which was their initial aim on entering the medical college. To pull a medical student into the laboratory he must be diverted from his first idea which, in 98 per cent. of the cases, was practice. Naturally the best qualified men are the most difficult to divert.

3. Increase the size of anatomy departments up to a university basis with not one but four or five professors in the department with a number of assistants and instructors and sufficient janitor service. This is the one thing that makes university departments of chemistry, etc., full of students, college graduates, willing to work four or five years to become a professional chemist with a small salary in the future. A better rate of pay will help the situation but not cure it. Fellowships and low paid assistantships are of little avail.

4. By preventing the proposed fifth clinical intern year of the medical course from becoming in all cases simply a clinical intern year, instead of largely a laboratory course in the case of many. The full-time clinical instructorship will appeal to even the few that might have come into labora-

tories, since they have all the advantages, etc., and in case of failure one can step right into practice. Whereas if a man fails after four or five years in the preclinical department he is almost unfitted for practice. It looks as if the medical schools must still for a long time recruit their laboratory teachers from the university science departments, and this is too bad, as American medical schools should be self-supporting in their teaching supply. . . .

21

1. Yes. Mainly lack of funds.

2. Not always. They go into clinical work, not infrequently into clinical laboratory work for a period of some years. They are aware that the time spent in this form of laboratory work is likely to bring material rewards in the future.

3 and 4. Behind any plan which promises success must stand a very large increase in funds available for increasing salaries and facilities for work. A small increase is of little avail. While no doubt other factors are important, nearly all can be traced back to the economic factor. An increase of 100 per cent. in salaries, so that \$10,000 or \$12,000 posts would be as common as \$5,000 or \$6,000 just now, would in time have a great effect. The common idea that the so-called full-time clinical man should receive twice as much as the full-time laboratory man is quite erroneous. Both should be well paid. If there is any discrimination it ought to be in favor of the laboratory man, as in the past at any rate he has had on the average the higher quality of brains. This has a definite bearing on the question why it is becoming so hard to get or to hold the best type of man in the laboratory branches. . . .

22

1. Insufficient means to provide living expenses for a group of untrained men. Insufficient means to maintain a line of promotion offering increasing income as men grow older and acquire increasing responsibilities. A widespread conviction that the highest places attainable do not provide a comfortable living.

2. No. A considerable proportion of the men in this department who have been desirable to hold have been attracted to clinical departments in universities or have taken up practice of medicine.

3. There should be a number of junior appointments (six to ten) paying the equivalent of \$1,000 to \$1,200 (in some instances with residence in the hospital). Several positions, at least four, ranging from \$2,000 to \$5,000. Salaries to heads of departments in fundamental sciences having closer approximation than exists at present to those attainable with reasonable success in other walks of life and particularly in clinical medicine. With existing conditions this requirement must be fulfilled in order to elevate the status of teaching in the community.

4. Recognition by the clinical departments that the training of men to fill the highest places in medicine or surgery requires a more intimate knowledge of pathology. A large proportion of those who are pursuing academic careers in clinical medicine should have one or two years as assistants in pathology. Provision for much more numerous junior places to train men both for clinical work and for a career in pathology.

ANALYSIS OF REPLIES

The replies often are couched in indefinite terms so that we cannot be certain that in every case we have correctly grasped the author's meaning. It would seem that at least three of the departments replying do not have assistants of any kind; that two, possibly more, have only student assistants; and that eight, namely, Hooper Institute at California; physiology at Stanford; anatomy at St. Louis University; pathology at Nebraska; physiology at Albany; physiology at Columbia University; physiology at Syracuse, and pharmacology at Western Reserve recently have not had vacancies in the full-time staff. It may be added that it is not always correct to infer that because a department has not been in

the market for assistants the conditions within the department therefore are satisfactory.

However this may be, there remain 125 departments which have recently been in quest of full-time assistants. Of these, fourteen, namely, anatomy and biochemistry at California; biochemistry and pathology at Stanford; pathology at Yale; anatomy, biochemistry, physiology and the School of Hygiene at Hopkins;² anatomy at Cornell; biochemistry and physiology at Jefferson; anatomy at Colorado, and physiology at Bowdoin, state more or less definitely that they have had no difficulty or no more than the usual difficulty in filling their vacancies. In many of these instances unusual circumstances are referred to, such as climate, funds or university relations, which, in the opinion of those interrogated, tend to compensate for recognized difficulties. One hundred and nine state definitely that they are unable to fill, or are having difficulty in filling vacancies, or are unable to hold men.

The second question, namely, "Do you succeed in obtaining as assistants the best qualified men from among those eligible?" was framed for the purpose of ascertaining whether students from preclinical departments, who seemed best able to develop the preclinical sciences, were entering and remaining in the departments of the preclinical sciences. The replies to this question show that of the departments that are manned by full-time assistants and within recent years have been in the field for men (126 in number) all believe either that they do not, or do not in general get as assistants the best qualified men, or that when they do get such men they cannot as a rule hold them longer than from one to three years, or they give a noncommittal answer, excepting one department in each of the following eight schools: Colorado, California (Hooper Institute), Stanford, Bowdoin, Hopkins (?), Michigan, Jefferson and Hopkins School of Hygiene.

According to the answers, the better men on graduation mainly go into practice; some go into commercial and hospital laboratories, while the pick of them go into the full-time clinical departments or research institutes. This also seems to be the fate of the promising men who enter the preclinical departments, usually to leave after one to three years of experience.

In our opinion these statistics leave no reasonable room for doubting that there is a paucity of satisfactory assistants in the departments of the preclinical sciences. The better graduates as a rule do not seek positions in these departments; or, having for one reason or another become members of such a department, they do not as a rule remain very long in it. The effect this deficiency in satisfactory assistants must have both on the quantity and on the quality of research accomplished in the fundamental sciences, not alone by the assistants themselves but also by the older and better trained men who are making or hope to make the preclinical sciences their life work, is so obvious as not to require comment.

The difficulty in filling vacancies and in holding men (Question 1), and the inability to interest the better men in careers in the preclinical sciences (Question 2), both are attributable to the same causes and, to refer now to Question 3, any plan calculated to lead into the preclinical sciences their fair share of the best qualified men must of course take these causes into consideration. The replies show, both by the causes assigned and by the plans proposed, that the situation is quite complex; many, indeed most, refer to more than one factor. The opinion, however, is nearly unanimous that insufficient salaries is one of the causes—that improvement in the salary situation alone is all that is necessary to relieve the immediate situation. It is referred to as a cause of the difficulty, or is mentioned as one of the ways of

overcoming the difficulty in all of the replies save two or three. Two of those interrogated (Nos. 27 and 28) are of the opinion that inadequate salaries are not the chief factor.³ The fault, though, is by no means entirely with the salaries of the assistants; for, even under present conditions, it seems possible in many of the schools to obtain excellent assistants who remain for a year or two in order better to prepare themselves for practice, for commerce, or for a career in one of the clinical departments. Rather, the main deterrent is the prospect that if one actually should achieve success, the final goal would fall far short of furnishing as large a salary as preclinical heads feel they are entitled to receive. To quote an expression frequently found in the replies—the salaries are too low "all along the line."

The answers make it clear that it is no longer true, if it ever was, that a man will choose an academic career when he knows that even if he should achieve distinction he would have to forego the prerogatives and comforts that now can be gained by any one of similar attainments in other walks of life who meets with a fair degree of success. It would seem to be the general opinion that a small increase in salaries would not suffice to check the movement away from pure science.

Two of those interrogated seem to fear that any *great* increase in salaries "would defeat its own end by attracting men by reason of their unfitness." This danger could readily be avoided if, as some suggest, beginners were tried out for two or three years on annual appointments before they actually were made members of a department. All that can be said with regard to this opinion is that the men occupying the preclinical posts that pay the largest salaries certainly are not any less productive than men in other places. We are of the opinion that research would suffer less if the goal were a living in ease and comfort rather than a constant effort to maintain a respectable standard of living.

A fruitful source of discontent apparently is the present movement to pay full-time clinicians larger salaries than the men in the preclinical branches. This subject is specifically mentioned in twenty-eight of the replies, and many others refer to it indirectly. It is pointed out that "a man who studies medicine will naturally be more attracted to the clinical branches where he can now find good opportunities for research and at the same time not cut himself off from the possibility of earning a respectable living;" that "the remuneration of men in the preclinical branches must be raised to that of men doing full-time work in the clinical subjects," "or their assistants will not only be deficient in number but especially inferior in quality." One almost gains the impression that some would actually reverse the situation, so far as salaries are concerned, so as to offset the natural tendency on the part of medically trained men to remain in the clinic and deal with practical things. Further comment on this topic is unnecessary; the replies accompanying the report make the situation quite clear.

But while insufficient pay "all along the line" evidently is the most important factor accounting for the paucity of preclinical assistants, there are other factors that are not without significance. A surprisingly large number are mentioned in the replies. This perhaps is to be expected. For, owing to the state of mind the unsatisfactory conditions in the university world tends to develop, aggravations which ordinarily would not be worth mentioning assume an importance to the individual that compels emphatic assertion. Furthermore, a questionnaire of this kind affords an opportunity to lay bare difficulties and differences which may be more or less local in their significance. In an effort to ascertain the fundamental difficulties it is essential not to attach

2. The questionnaire was sent to but one of the departments of the School of Hygiene.

3. These are the two replies that are quoted in addition to the reply that has been selected as representative of opinion in its school.

undue weight to such matters. A few of the factors mentioned as partly responsible for the present situation that seem worthy of more serious consideration are listed below, together with the running comments of the committee.

1. Insufficient staff—junior and senior.
2. Lack of facilities.
3. Difficulty in finding time for research.

If the necessary assistants could be found, these causes of discontent could be remedied by increasing budgets.

4. Supply not equal to demand due to call for men in the industries and in developing schools.

This state of affairs may be temporary, but in any event points to the need of increasing the number of men preparing for a career in science. Possibly, as most believe, the supply could be increased by increasing salaries and budgets, though changes in educational methods may also be necessary.

5. Dearth of men qualified to fill positions.

If true, either training is at fault, or it may be due to failure of men to prepare themselves for a scientific career because they know nothing of it, or, knowing of the career, they regard it unattractive or without opportunities or promise.

6. The men are committed to clinical work from the beginning.

This could be unqualifiedly true only of men who are slated for definite positions in practice. All others, after learning to know something of research, might be swayed to take it up.

7. Attractiveness of clinical work.
8. Majority prefer doing their work in relation with patients.
9. Greater pay and opportunities in full-time clinical departments, together with the possibilities of stepping into practice:
 - (a) If productive ability should cease.
 - (b) If promotion is blocked, or
 - (c) If larger returns are wanted.

Probably true; and if true it would be necessary to increase the attractiveness of the *fundamental* departments if the superstructure is not to topple over; this could be accomplished only apparently by supplying more funds for all purposes, and especially for the purpose of removing any discrepancy in salaries.

10. Possibility of doing as much research while practicing as while teaching.
11. Nonteaching positions offer better opportunities for research.
12. Commercial laboratories not alone offer more pay but the opportunity for research with no teaching.

This is true, at least in part, and such places will always be sought by those who are interested in research but not in teaching. Judging by the emphasis all have laid on investigation there is no doubt but that the vast majority of men who go into science do so because they are interested in research primarily. It must, therefore, be recognized that the best investigators will not go into or remain in university work unless ample time and every facility are provided for research. In addition, there should be university positions to take care of unusually productive men who do not care to teach. This should not be left solely to research and commercial institutions.

13. Falling off in attractiveness of teaching and research as a learned profession.
14. Few interested from the purely scientific side.

We doubt if teaching is any less attractive now than it ever was, present conditions merely serving to emphasize a condition which always has existed in the sciences. The indications are rather that interest in research in pure science

by no means has waned; all are pleading for an opportunity to do more, and recommend that research be used as the lodestone by which to attract men into the preclinical sciences as a career.

15. Attitude of the public toward universities.
16. Commiseration.
17. Lack of academic recognition.

It is a mistake to believe, as many apparently do, that the average teacher and investigator is going to exert any influence over any but his immediate colleagues and students. Personal characteristics, but especially financial limitations, are largely the factors at the bottom of these sources of discontent.

18. Unsympathetic attitude of clinicians toward research.

Men holding this attitude toward research in general have no place in our schools.

19. Insecurity of tenure of office.
20. Autocratic university administration and university politics.
21. Treatment of men in departments as subordinates rather than as colleagues.

These are not very often referred to, though a number include in their plans for improving conditions security of tenure after ability has once been demonstrated by a probationary period.

22. Medical curriculum too rigid.
23. State board rule requiring an intern year and not permitting a laboratory year in its stead, limits choice of students.

These are frequently mentioned; they seem to discourage the preclinical heads because they reduce the opportunity for training advanced students, a type of teaching to which none object.

Without going into further detail, the main impression this list leaves is that the majority of men are attracted to the preclinical sciences because they are interested in research primarily. Therefore, to interest men in these subjects and to keep contented those who have already committed themselves to them, it would seem to be necessary not alone to increase salaries but also to give to those who are fitted for investigation the maximum of time and facilities for the conduct of such work, relieving them as far as possible of teaching and of departmental routine. This again becomes a matter of finance.

The opinion frequently is expressed that only rarely will it be possible under the present circumstances to obtain recruits, for some of the preclinical sciences, at least, from among medical students; that in the future it might be necessary or even advisable to depend on philosophical students as a source of supply. Some go so far as to maintain that we shall have to go outside of the medical sciences for men. If the preclinical departments were departments of a university, as they should be and often are, there is no reason why they should not, as they do now, choose assistants from their philosophical students and graduates as well as from their medical students and graduates. But to deprive the heads of the preclinical departments of the opportunity of training investigators, of turning out their own students, would merely have the effect of adding another source of aggravation to the many they are contending with already.

But, to judge by the replies, to substitute graduates in philosophy for graduates in medicine as assistants would merely have the effect of postponing the evil day; for it would seem that, recognizing the power of the M.D. degree, as many of the former, who are now in the preclinical sciences, as find it possible carry work toward that degree and then go into practice. Furthermore, it will be noted that

it is not alone the "medical professors" who are dissatisfied, but the "lay professors" as well.

Finally, attention might be drawn to a suggestion that is frequently found (in at least twenty-two of the replies), in connection with Questions 3 and 4, with regard to means by which men might be led to enter a preclinical science as a career, because it is one which possibly could be put into effect, though, perhaps, it should not be tried until the main difficulty has been met. This suggestion is to put at the disposal of the preclinical departments a number of attractive assistantships and research fellowships so that a man who wished to obtain additional training in one of the fundamental medical sciences, either for the purpose of better preparing himself for practice or for a post in a clinical department, would find no financial obstacle in his way. It is felt that some of the men availing themselves of such appointments might become sufficiently interested to give up their first intentions and become full-time members of a department of a preclinical science. In this way, possibly, depletion of the fundamental departments through transference of men to clinical departments could be avoided.

CONCLUSIONS

The committee is convinced that:

1. There is a great paucity of satisfactory assistants in the preclinical departments.
2. Insufficient immediate and prospective financial support of the preclinical departments as compared with financial support obtainable in other directions is the main, though perhaps not the only, deterrent.
3. This paucity is seriously hampering the development of the preclinical sciences and, through them, of medicine as a whole.

RECOMMENDATIONS

1. In the opinion of the committee, the only effective step the council could take in the matter would be immediately to inform of the actual state of affairs those who alone have it in their power to remedy the situation, namely, the trustees and executives of universities, the medical profession and public-spirited citizens.
2. In the committee's judgment, the most effective and only practicable way of accomplishing this end would be to publish the foregoing analysis of the replies to the questionnaire, together with a representative reply from each of some twenty to thirty schools, editing the replies only to the extent of obscuring the identity of the writer and of eliminating irrelevant matter.

Occupational Diseases.—In a monograph on the occupational factor in tuberculosis, Dr. G. M. Kober states that diseases of occupation are everywhere assuming more and more importance, not only to wage earners and employers, but also to physicians, who, in order to make an early diagnosis and give the patient the full benefit of treatment, should know the conditions injurious to health under which our fellow men and women live and work. In countries and states where reports of certain occupational diseases are compulsory, it is quite possible to secure fairly reliable data as to the number of cases of specific industrial poisoning. Such special investigations are all the more important when it is remembered that even the most complete statistics fail to reveal all the factors which influence the health and longevity of operatives. Great differences are found in the conditions under which the work is performed, some of which are entirely avoidable, while others are not, and it is hardly fair to characterize certain trades as dangerous when experience has shown that no harm results when proper safeguards have been taken. In the consideration of this question, the personal element of the workmen, their habits, mode of life, and their physical fitness cannot be ignored.—*Pub. Health Rep.*, March 26, 1920.

Social Medicine and Medical Economics

PROPOSED PUBLIC HEALTH REORGANIZATION IN NEW YORK

Senate bill 1533, introduced into the New York Legislature on March 25, provides for an extensive reorganization and amplification of the state public health machinery. It might be regarded as an alternative and substitute for the Davenport Compulsory State Health Insurance Bill. It seeks to remedy alleged evils through the development of state public health rather than through compulsory health insurance. The bill provides that the board of supervisors (which corresponds in New York to the county commissioners in other states) of the county, with the approval of the state commissioner of health, may establish such a county, or any part of a county, as a health district and in such event shall appoint a board of health for each district consisting of five members, at least one of whom shall be a physician. The members of the board are to receive actual expenses but no salary. The board is authorized to appoint a district health officer possessing such qualifications as the public health council (an advisory body to the state department of health) may prescribe. His salary is to be fixed by the district board of health. The board of supervisors is authorized to establish a health center, or centers, which shall include (1) the erection of a new hospital, or arrangements with existing hospitals, with special provisions for hospital treatment of tuberculosis and other communicable diseases, maternity cases, children and mental diseases; (2) clinics for outpatients, including maternity, prenatal and child welfare clinics and clinics for tuberculosis, venereal diseases, mental and nervous diseases and defects, dental clinics, schoolchildren clinics and general surgical and diagnostic clinics; (3) for clinical, bacteriologic, roentgen-ray and clinical laboratories, auxiliary to the state laboratories and affording facilities for the diagnosis and treatment of disease; (4) for public health nursing service for all parts of the district; (5) for cooperation with the department of education in securing proper medical supervision and medical school inspection for schoolchildren; (6) for a periodic medical examination for such inhabitants of the district as desire it and are willing to pay a proper charge therefor; (7) for headquarters for all other public health, medical nursing and other public welfare agencies of the district. In addition to levying taxes for these purposes, the board is authorized to accept and hold in trust for the county any gifts or bequests that may be made for this purpose.

The board of supervisors is authorized to appoint a board of managers of the health center consisting of seven members, one of whom shall be the county judge, one, a woman and two, legally qualified physicians. The board of managers is authorized to appoint a superintendent to the health center and to fix his salary, to exercise general management of the center and to make rules and regulations for the care and treatment of patients and the fixing of fees and salaries. Compensation for physicians and surgeons rendering services in hospitals and clinics is to be fixed by the board of managers. The board is also authorized to erect buildings, to appoint medical boards and members of the various staffs, to employ public health nurses, to equip and maintain the health center, to keep all records, and to collect and disperse all money received. The city council of any city in the state is authorized to establish one or more health centers in the city and to exercise all of the powers conferred on the county boards of supervisors.

The last section of the bill provides for state aid in the creation and administration of health centers. In the con-

struction and equipment of hospitals, one half of the cost, not to exceed \$750 a bed nor one bed for each 500 of the population affected, is to be defrayed by the state. A state grant is provided of 75 cents per day for each free patient and for one half of the cost of the installation of the outpatient clinic, not to exceed \$5,000, for the expenses of free clinical treatment, not to exceed 50 per cent. of the cost nor an average of 20 cents per treatment. The state will also pay one half of the actual cost of laboratories, not to exceed \$1,500 for the initial installation and equipment nor \$3,000 for the maintenance of each laboratory. The state is to contribute at the rate of 10 cents per capita per annum toward the salaries of deputy health officers in health districts with a population of less than 1,500, and of 5 cents per capita per annum in districts with a population of from 1,500 to 3,000, this amount to be in addition to the salaries paid the district health officers by the county board of supervisors. The work of all health centers, hospitals, clinics and laboratories is to be subject to inspection and standardization by the state department of health, and state grants are to be paid only on the written approval of the state commissioner of health following such inspections. One hundred thousand dollars is appropriated for expenses to be incurred by the state department of health in putting this act into operation.

This bill adroitly combines in one measure provisions for county boards of health and whole time health officers, county hospitals, local health centers and dispensaries, public health nurses and local laboratories and opportunities for periodic medical examinations for the public. It aims to meet the need for better medical services, especially in rural districts, through the development and expansion of state public health organization and activities rather than by the creation of a system of compulsory health insurance. The creation and administration of departments or boards for the conservation of the public health have come in the last fifty years to be recognized as a legitimate function of the state. Compulsory, state supervised insurance is a new and untried plan in this country. If the proposed elaboration and extension of state public health functions and activities will be as effective in correcting the alleged evils as the proposed compulsory health insurance plan would be, then the burden of proof is on the proponents of compulsory health insurance to show why their plan should be adopted rather than that of the extension of state public health functions with which the American people are familiar.

NEW YORK CHAMBER OF COMMERCE OPPOSES COMPULSORY HEALTH INSURANCE

The New York Chamber of Commerce at a regular meeting held April 1 unanimously adopted a report presented by its committee on insurance, opposing the bill introduced by Senator Davenport providing for compulsory state health insurance. The committee recommended, a year ago, that a commission be created to make a comprehensive study of health insurance on behalf of the state. This recommendation was not followed. Further study of the subject has convinced the committee that compulsory health insurance attacks the problems involved from the wrong point of view and is economically unsound and unwise. In support of this conclusion the committee submits nineteen general statements, from which we quote:

It is opposed to sound public policy in a democracy, in fostering objectionable class distinctions and a dangerous tendency toward a stratification of industrial society.

It is opposed to public policy in favoring a further encroachment on private rights and privileges, including the most personal concerns of the individual, and the supervision,

control and direction of the person in matters of health and welfare.

It is a danger to democracy, in that the promises made are impossible of fulfilment, and on this ground will ultimately create an unwholesome industrial unrest.

It is a delusion in that the poorest poor, who are most urgently in need of sympathetic medical and financial support and assistance, are largely if not wholly outside the sphere of social insurance activities of any and every kind.

Such demand for compulsory health insurance as exists has been artificially created by a skilful propaganda.

It is at best a palliative, and does not reach the seat of the difficulty.

It does not promote the health of the individual, but rather fosters a tendency toward malingering and an undue prolongation of minor ailments for the purpose of wrongful gain.

Experience in other countries shows that medical treatment under its rules results in a standardized method of mediocre practice—the doctor who gives his whole time to the service reduces his profession to a mere trade; the doctor who gives only part of his time to the practice is bound to give it indifferent attention.

Experience abroad has also shown that medical practice under this system tends strongly toward a system of public medicine, opinion being divided as to whether under such a system private practice should be allowed at all, or whether the system should be universal; in other words, whether the doctor should become a state employee, leaving private practice and the work of the specialists to the few who are unwilling to submit themselves to state control.

All the estimates in England have been more or less at variance with actual experience. The state contribution has been very much greater than had been assumed would be necessary at the outset.

Compulsory health insurance is an elaborate bureaucratic scheme which controls wage-earners' lives and wage-earners' incomes. The hope held out that the institution to be created will be thoroughly democratic and, apart from the overhead charges, self-sustaining, never has been and probably never will be realized. Control of essentials soon passes into the hands of the state authorities, with a corresponding increase in the power of bureaucracy.

Medicolegal

Mental Reservations of Illegal Practitioner Not Recognized

(*Pickard v. Commonwealth (Va.)*, 100 S. E. R. 821)

The Supreme Court of Appeals of Virginia, in affirming a judgment of conviction of defendant Pickard, a colored man, says that he was convicted and sentenced to pay a fine of \$250, and to confinement in jail for three months, for practicing medicine without having obtained a certificate from the state board of medical examiners. He had been for a number of years engaged in selling, through the agency of a drug store, certain proprietary medicines of his own manufacture. He maintained an office, where his patrons would resort to consult him, and he would advise them which of his remedies, if any, was suited to their case, and direct them to the drug store where it could be bought. Subsequently he had his business incorporated, and sold his medicines direct to the trade without the intervention of a druggist. He described his general course of business substantially as follows: When a customer would call for a particular medicine, he would sell the remedy wanted, while others would describe their symptoms, and he would prescribe which of his medicine would suit the case. In such instances he stated that he made no charge for advice and received only the price of the medicine.

A witness for the commonwealth testified that her son, aged 5 years, was ill, and she took him to the office of the accused for medical advice and treatment; that he placed the child on a table and felt his pulse and examined his tongue for a few minutes, and said: "Well, I tell you this child has the kidney trouble, and has it right bad," and if I didn't attend to it right away it would go into meningitis or something bad." The witness requested him to prepare the right medicine for the child; but he said it would take him a long

time, and told her to come back the next day. She returned accordingly and paid him \$2 for the medicine. She had heard that he could tell what was the matter with the child as soon as he saw it, and went to his office to consult him as a physician. He did not tell her the name of the remedy, but said he would prepare a medicine that would be suitable treatment. After taking the medicine the child grew worse, and she called the accused to the telephone and told him of the child's condition. He advised her to give him one or two tablespoonfuls of "Syrup of Figs" until it acted, and then give him his medicine again. The accused in essentials corroborated the testimony of the witness. He admitted that he diagnosed the case and prescribed for the patient, and compounded and supplied the remedy for compensation. He moreover acknowledged that he had done and was then doing the same thing for numerous other patients; that he claimed and announced to the public generally his ability to diagnose diseases and compound and furnish remedies for their cure. Yet he qualified his statement by alleging that he did these things, not as a physician, but to advertise his medicine, and charged for the medicine, and not for examinations and advice. He confessed that he had never been examined by the board of medical examiners, and held no certificate from them, and had no right to practice medicine in the state. The verdict of the jury was fully sustained by the evidence.

The law does not recognize the mental reservations of the accused, by which he bunglingly attempted to escape the consequences of his flagrant and habitual violations of the law. The object of the statute is to protect the public against just such impostors. A number of exceptions were taken by the accused during the progress of the trial to rulings of the court, but they did not call for special notice, since the case plainly came within the rule that, when the appellate court can see from the entire record that no other verdict could rightly have been found under correct instructions, or that the accused could not have been prejudiced by the rulings of the trial court, it will not reverse the judgment and set aside the verdict.

Hospital Treating White Patient as a Colored One

(*Collins v. Oklahoma State Hospital et al.* (Okla.), 184 Pac. R. 946)

The Supreme Court of Oklahoma, in affirming a judgment sustaining a demurrer to the petition in this action for alleged libel holds that a cause of action for libel cannot be maintained against a hospital for the insane on account of the act of its officers and employees in placing a white patient in that part of the institution set apart and used for colored patients. The court says that it was alleged in the petition that the defendant state hospital was the successor to a sanatorium company; that the plaintiff took his daughter, who was a white person and insane, to the sanatorium company for treatment, she being received and placed in a ward used by the white people; that a few days thereafter those in charge of the institution placed her in a ward set apart for negro patients, and entered on its records opposite her name the word "colored," and thereby held her out to the world as having negro blood, which condition continued about six months. To write of or concerning a white person that the person is colored is libelous, in and of itself, in Oklahoma. But, under the allegations of the petition, the writing of the word "colored" opposite the name of the patient, on the records of the institution, was not a publication, as it was not alleged that it was ever seen by any one, or that the books had ever been examined by any one whatsoever, or that the word thus written had ever been seen or read by any person whomsoever. This was necessary before an action of libel could be based thereon, so far as the writing of the word was concerned. Necessarily the person who wrote the word in the books must have seen it, but that person must have been the agent of the corporation, if the act was said to be the act of the corporation, and such agent was for that purpose the corporation itself. It can hardly be said to be a publication of a libel for one to show the libelous matter to himself.

Nor can the court say that placing a white patient in that part of the institution set apart for colored patients comes

within the application of the Oklahoma statute so as to make it libelous. However, if it were libelous, the court doubts exceedingly whether, under the provision of the statute, the plaintiff would have a cause of action therefor.

For a second cause of action it was alleged that the defendants did commit a wrongful libel by publishing a written statement made by them to the plaintiff, in the form of a letter which stated that, in answer to one of his, I "beg to say that Lee Collins (Col.) is in fairly good mental condition; also good physical condition," etc. But the court is of the opinion that the entire contents of this letter was privileged. It was written by the superintendent of an institution having in charge the patients of the state, helpless and unfortunate as they were, to the father of one of the patients, no doubt grievously interested in that patient's welfare. The law as well as the dictates of common humanity imposed on the superintendent of that institution the duty of answering inquiries of such character, and likewise the duty of answering fully, fairly and freely as to the condition of the patient inquired about. As the court views it, the subject-matter of the letter was Lee Collins, and it was the duty of the superintendent to write to her father, not alone as to her mental and her physical welfare, but any other fact or circumstance which he should know in order that he might be the better enabled to aid and assist in her comfort and welfare. If she was regarded at the institution as colored, it was his duty to inform the father of that fact, so that, if an injury was being done to her, it could be remedied; and if the letter, which was the publication complained of, was protected by the rule of being qualifiedly privileged in all other things save and except the use of the abbreviated word "Col.," then the entire subject matter of the letter was likewise within the rule.

- Review of Literature on Respiratory Diseases. L. C. Schroeder, New York.—p. 231.

Dilation of Colon in Children.—Myers is of the opinion that spasm is a cause of dilation of the colon. He reports one case in a child, aged 4 years, which was diagnosed both clinically and with the aid of the roentgen ray. Constipation dated from infancy and had been persistent. All sorts of drugs were tried, but no attention was given to the preponderance of starch in the diet. Assuming that spasm was playing a rôle in this condition, the child was put on increasing dosages of atropin, starting from 5 drops of a 1:1,000 solution, until the child complained of dryness of the mouth. Gradually, well done toast, cooked fruit and green vegetables were added to the diet and the atropin was decreased. The constipation ceased after the spasm was relieved and normal defecation followed. Five other similar cases are cited in which the starch free diet and atropin yielded equally good results.

Osteogenesis Imperfecta Congenita.—The study of the bone in the case reported by McClanahan and Willard showed evidence that the osteoblasts rising from vascular fibrous bone marrow, because of insufficient nourishment or some toxic influence, did not develop properly, but remained polygonal and later underwent metaplasia into osteoclasts. The patient was only 3 months old. Death occurred from exhaustion. According to the authors, this patient is the youngest dying from this disease on who a necropsy was performed with subsequent histologic study of the bones. A complete report of the findings is made.

Chondrodysplasia: Multiple Cartilaginous Exostoses.—Three members of one family were victims of cartilaginous exostoses. They were aged 7 and 29 years, and 20 months, respectively. The oldest patient was the father of the other two patients. The mother and another daughter, 5 years of age, were not affected. The bones involved were the tibia, femur, humerus and scapula. The cases are reported in detail, and the literature is reviewed.

Calcium Metabolism of Infants and Young Children.—In this paper the authors discuss the calcium metabolism of older children taking a mixed diet. Both healthy and rachitic children were the subjects of this study. With children taking a mixed diet, the absorption of calcium per kilogram was lower than that of infants taking modifications of cow's milk, averaging when the intake was adequate, 0.055 gm. of calcium oxid per kilogram. An intake of at least 0.09 gm. of calcium oxid per kilogram is necessary to insure a good absorption by children taking a mixed diet. The best absorption of calcium oxid occurred when the intake of fat exceeded 3.0 gm. per kilogram, and when, at the same time, for every gram of fat there was in the diet from 0.03 to 0.05 gm. of calcium oxid. When calcium in the form of chalk mixture (calcium carbonate) were added to the diet, there was a greatly increased absorption of calcium. When calcium was added as calcium acetate or as calcium phosphate the absorption was not increased. The excretion of calcium was not so closely related to the intake of calcium as in the case of infants taking modifications of cow's milk, and was not at all related to the fat intake. The calcium absorption of children with active rickets was lower than that of normal

children, even though the calcium intake was ample. The calcium excretion in the stools was somewhat higher than the average excretion in the stools of normal children. During recovery from rickets, the absorption of calcium was higher than the average for normal children. This improvement accompanied the taking of cod liver oil or additional butter with a diet containing an ample amount of calcium. The calcium excretion in the stools of children recovering from rickets was lower than in the stools of normal children. Cod liver oil increased the absorption of calcium, except in cases in which the intake of calcium or of fat was very low. The substitution of vegetable fats for milk fat did not affect the calcium metabolism of children taking a mixed diet.

Renal Function in Scarlet Fever.—The observations made by Veeder and Johnston in seventeen cases of uncomplicated scarlet fever and in two cases of scarlet fever with nephritis proved that, as a routine measure, the urinary examination for albumin, as ordinarily carried out in scarlet fever, is of more value than the functional tests in announcing the onset of an impending kidney complication.

Comparison of Action of Roentgen Rays and Radium.—Soiland believes that the roentgen rays offer decided advantages in the treatment of lesions covered by, or affecting, the epithelium. On mucous membranes or in cavities where soft tissues predominate radium becomes the element of choice. This is particularly true in lesions involving the mouth and upper respiratory tract, the vagina, the uterus and the rectum. The best results in general are obtained by a judicious combination of both.

Abducens Palsy: Transplantation of Vertical Recti in Three Cases.—O'Connor states very emphatically that in cases of abducens palsy relief is possible, in spite of statements to the contrary in most textbooks on ophthalmology. Therefore, these patients should not be dismissed as incurable or told to wear a patch over one eye permanently but should be referred to the ophthalmologist early in order that the progress may be watched and operation done as soon as it is certain that power is not returning. The author describes his method of procedure and reports cases.

Some Phases of Kidney Secretion.—The question is raised by Fisher of the mechanism by which water is secreted by such a secreting parenchyma as a kidney. The experimental evidence is reviewed which indicates that only "free" water can be separated from the blood and that the separation of such water costs the kidney no work. This supports the conclusion that such separation is a mere filtration process,

and since the secreting parenchyma of such an organ as the kidney is a hydrated colloid which has properties closely akin to a solid hydrated soap, the filtration properties of such a soap (sodium stearate) were studied to see whether any analogy exists between its behavior and what may be observed biologically. Hydrated sodium stearate allows water to pass through it under slight hydrostatic pressure, the ease of such passage being increased as the concentration of the hydrated colloid is lowered. While "free" water passes readily through such a hydrated colloid, water tied to a hydratable colloid (liquid sodium oleate) cannot. Salt solutions lead to a greater filtration of water than plain water, and this (a) according to their concentration and (b) their kind, generally speaking. The higher the concentration of any salt, the greater the filtration of water. On the other hand, at given concentration, salts of ammonium or potassium produce less filtration than salts of sodium, and these less than those of magnesium or calcium. The theory of the action of these effects is discussed, it being pointed out that because of the existent differences in chemical composition of fatty acids and of the polymerized amino-acids known as protein it is possible in the former to produce only one series of salts as different bases are introduced into the fatty acid. In the case of the proteins a similar series may be produced, but because of the existence in the latter of NH groups, a second may be produced, through the linking of acid with these groups. Colloid chemical and physiologic behavior are, then, an expression of the solvation and solubility properties of the different compounds thus formed. The dangers of applying without due reserve indicator methods and the laws of dilute solutions of electrolytic dissociation, etc., to the normal cells and fluids of the body but not to their secretions is reemphasized.

Collection of Urine from Each Kidney Separately.—Hopkins and Quinby use the ureters as a receptacle of the products of one kidney while the normal relations between the bladder and other kidney are maintained.

Influence of Male and Lethal Factors on Production of Twins.—The presence of lethal factors in the ovum or spermatozoon is regarded by Davenport as an influence in the fertilization and development of an ovum. Lethal factors may be brought into the zygote by the egg alone, by the sperm alone, or by both. They are not found in all the germ cells; it may be, in only a small proportion of them. When they occur in the gametes of both consorts, small families with some feeble children may be expected. But when they are absent in the germ cells of both parents, then,

in a good environment, the fertilized egg will develop vigorously with good prospects of reaching maturity. It is in such families that any tendency toward double ovulation will be expressed in the production of healthy twins. Statisticians have long recognized that the proportion of twins is larger in highly fecund families than in those that produce few offsprings, and this is now seen to be because in such highly fecund families the germ cells contain few lethal factors and there is a larger chance that double ovulation will result in twins. Davenport is convinced that it is thus clear where the male factor comes in in twin production, for the father can, as much as the mother, determine whether both of a pair of simultaneously ovulated eggs shall be fertilized, and whether or not they shall receive lethal factors.

Rebuilding Broken Arches.—A plan of treatment to rebuild the broken arch, while the feet are in daily use during the process of rebuilding, is reported by Cross. The plan consists of a system of exercises on specially designed exercising appliances, massage, manipulation, mechanical force, static and dynamic force, support, and then gradual removal of the support. In rebuilding broken arches, the aim of this system of treatment is to reconstruct the arch and to strengthen the foot that it will stand ordinary usage, without the aid of an arch support. Cross emphasizes that arch supports, at best, are but splints and should be used only as such. Constantly wearing any kind of a rigid splint weakens the muscles because free action is restricted. This is especially true when metal splints, in the form of arch supports, are worn under the feet, and the general results from their use is a degree of atrophy of some muscles and weakening of others. The process of rebuilding broken arches by this system aims to follow the same lines followed by engineers to replace a bridge span, or a house foundation, that is out of alignment. A careful drawing is made of the foot and this is surveyed to determine the degree of distortion or displacement. Then begins a system whereby the broken arch is blocked up or strapped up by degrees, as rapidly as possible with comfort, until normal function is restored. Clumsy and freak shoes are not a part of this system of treatment. Any shoe the patient selects which is long enough and wide enough can be worn.

Pregnancy Complicated by Large Fibroid Tumor.—The point made by Applegate in connection with the report of this case is, that sterility from any of the well known causes, including abnormalities of position of construction of the uterus, tubes or ovaries, faulty internal secretions, and hyperacidity of the vaginal secretions, may be regarded at least as a predisposing cause of fibroids of the uterus. In other words, absence of the childbearing functions favors hyperplasia of the loosely constructed involuntary muscle fibers and connective tissue cells of the uterus.

Case of Wladimiroff-Mikulicz Operation.—This operation consists in the removal of the tarsus and of the distal end of the bones of the leg and then placing the foot in a marked equinus position in such a way as to transform the walk from plantigrade to digitigrade. The indications for this operation are tuberculosis of the tarsus and ankle, chronic ulcers of the heel, fractures accompanied by osteomyelitis of the calcaneus and neighboring bones, as in the case described by Vegas. Of late indications have been extended to include the lengthening of limbs shortened by pathologic luxations in the coxalgia or ample resections of the knee followed by shortening of the member in advanced equinoparalytic feet.

Treatment of Bronchial Asthma with Vaccines.—Of a series of ninety patients examined and in whom a diagnosis of bronchial asthma was made, eighty-one have been treated with autogenous vaccines by Hutcheson and Budd. So far as possible, those cases were selected in which obvious and accessible foci of infection had been removed. Most of these patients had suffered over a considerable period and were well versed in the various cures, while in many instances one or more operations on the nose, throat or sinuses had failed to give relief. Where the first series of injections was ineffective, if possible, a second vaccine was prepared and administered and this was also done in a number of cases after relapse had occurred. In fifty-three cases (74.6 per cent.) there followed the administration of the vaccine either complete freedom from asthma or a definite decrease in the frequency and severity of the attacks. The longest duration of complete relief was three years. The longest period of relative relief was four years and two months. In eighteen cases (25.4 per cent.) no definite benefit was derived from the vaccine. In none of these cases, however, was the treatment repeated after the first series of injections had failed.

Tests for Nitrogen, Nitrites and Tryptophan in Urine.—The most important alterations in the original technic of the Kjeldahl method made by Fearon concerned the incineration. He found that a mixture of sulphuric and phosphoric acids gave a much better result than sulphuric acid alone. The following mixture is recommended: sulphuric acid, 100 c.c.; phosphoric acid, 200 gm.; copper sulphate, 5 gm. The mixture is best made by dissolving the phosphoric acid and the copper sulphate in the minimum amount of water, and then adding the sulphuric acid. The amount required for incineration will depend very much on the material under examination. Generally, from two to three times its volume will be sufficient. For extensive work the steam distillation method has been found the most satisfactory. Rapid estimations can be carried out very well by the Cole method of distilling with alcohol. For titrations, methyl red, 0.1 per cent., was found to be a very good indicator. The following is stated to be a simple test for nitrites in urine or similar fluids: To a few cubic centimeters of strong sulphuric acid in a test tube a very small quantity of carbazole is added and well shaken. If the sulphuric acid is pure, no color

change will be observed. Then, on adding a drop of urine, if nitrites are present, a deep green color will develop. The test is extraordinarily sensitive, and will show nitrites to the extent of about one part in half a million. If urine containing tryptophan be treated with excess of the glyoxylic reagent and a drop is added to strong sulphuric acid, the tryptophan condensation body interacts with the nitrites of the urine to give a deep green color. This test is not given by indol or skatol.

Bacteriologic Characteristics of Tubercle Bacilli from Different Kinds of Human Tuberculosis.—The main objects of Griffith's investigations were (1) to determine by the examination of unselected cases the relative proportions of the human and bovine types of tubercle bacilli in different kinds of human tuberculosis, and (2) to ascertain the frequency of occurrence and the distribution in the human body of variant strains of tubercle bacilli. Of 1,068 persons examined, 803 showed human bacillus infection; 194 bovine bacillus infection and five a mixed infection. Of various regions involved, the examination showed that bovine infections occurred as follows: Bones and joints, 19.7 per cent.; genito-urinary organs, 17.65 per cent.; cervical glands, 46.3 per cent.; meninges, 20 per cent.; scrofuloderma, 34.65 per cent.; lupus, 48.9 per cent. As to the age periods, bovine infection occurred as follows: during first five years of life, 37.55 per cent.; from 5 to 10 years, 29.45 per cent.; from 10 to 16 years, 14.66 per cent.; after 16, 6.25 per cent.

Inagglutinable Form of Shiga's Dysentery Bacillus Derived from Agglutinable Culture.—An inagglutinable strain of Shiga's bacillus was experimentally produced by Benians from an agglutinable strain by subcutaneous inoculation into a guinea-pig of the agglutinable bacteria suspended in mucilage of tragacanth. This inagglutinable bacillus (as

isolated from a separate colony), from time to time threw off agglutinable strains, especially soon after it was first isolated. The inagglutinable colonies were of two types, clear and opaque, on agar, but not distinguishable in broth cultures. The inagglutinable strain usually sedimented both in broth and saline. The inagglutinable strain failed to absorb agglutinin from a standard serum; it also failed to produce agglutinin when injected into rabbits. The agglutinable strain, derived from the inagglutinable, absorbed agglutinins entirely from a standard serum; on injection into rabbits it produced an agglutinating serum. Both strains were highly pathogenic for rabbits, the inagglutinable strain apparently more so than the other. Rabbits immunized against either strain were protected against a lethal dose of the other strain. In the animal injected with the inagglutinable bacillus an immunity developed against both agglutinable and inagglutinable strains without the production of any agglutinins. The development of agglutinins is not, therefore, necessarily a part of the processes of immunity. The inagglutinable strain was much more rapidly destroyed by the bactericidal bodies of the serum than the agglutinable. The guinea-pig inoculated with the bacteria embedded in mucilage formed no agglutinins or demonstrable protective antibodies. It is suggested that the experiment throws light on two clinical conditions: (1) chronic typhoid abscess; (2) the "carrier" condition of enteric and dysentery bacilli in the alimentary system.

Streptococcal Ulcerative Endocarditis of Aortic Valves in Infant Aged Six Months.—The total duration of fatal illness of the infant whose case is cited by Dible was only eight days. The condition developed while the child was in the hospital, suffering from crusted impetiginous sores on the head and upper part of the chest, and emaciation; there was also a discharging ear. It was noted, on admission, that the child was small. It frequently vomited its feeds, and also suffered from diarrhea. Under treatment the general condition improved, and three weeks after admission the sores on the head and body were healed, the diarrhea had ceased, and the general condition was improving. This improvement continued until the twenty-seventh day of residence in hospital. Up till this period the temperature had been within normal limits, but on the evening of this day it commenced to rise and on the following evening reached 101 F. During the six succeeding days the temperature oscillated irregularly between normal and 102 F., usually remitting in the mornings. No cause for this acute illness was discovered, and on the seventh day of its duration the child died rather suddenly. The examination of the thoracic and abdominal viscera showed the presence of moderate bronchopneumonic consolidation of the lower lobes of both lungs. The spleen was enlarged and somewhat soft, but not diffuent. The kidneys showed numerous well marked miliary infarcts of recent date, a number of which contained minute centers of suppuration. The heart weighed 30 gm.; its external surface, and that of the pericardium, was normal. On slitting up the cavities, the posterior cusp of the aortic valve showed recent acute, ragged, friable granulations, situated somewhat below the line of contact of the cusps; a similar patch of granulation was present on the wall of the ventricular septum below the valve. The affected cusp was found to be perforated, and the interventricular septum nearly so, the process having reached as far as the endocardium of the right ventricle, but not having perforated it. The other valves and cavities of the heart were healthy. None of the other organs available for examination showed changes worthy of note. Histologic examination of a piece of the vegetation, and sections of the infarcted areas of the kidney, showed very clearly, however, that the infecting organism was a streptococcus. The interest in this case lies in the fact of the extremely early age at which the affection occurred, and of its acute course. It was clinically unconnected with the gastro-intestinal disturbance for which the child was admitted, since the acute symptoms were only developed at the end of the period of stay in hospital when the impetigo and gastro-intestinal condition had disappeared. This case does not come within the category of the so-called "rheumatic" form of malignant

endocarditis which is met with in childhood, and in which the necropsy findings differ only in degree from those of "simple" endocarditis; it rather corresponds to the more virulent of the adult types of endocarditis associated with the suppuration of infarcts derived from the diseased valves.

Tobacco Amblyopia in a Woman. M. L. Hine.—p. 597.
*Case of Juvenile Tabes. D. Kerr.—p. 598.

Cytology of Pleural Effusion.—Page points out that a predominance of polymorphonuclear neutrophilic cells occurs not uncommonly in chronic pleural effusion complicating pulmonary tuberculosis. When it occurs, in the absence of secondary infection of the fluid, it suggests the possibility of hydropneumothorax being present; probably it may occur without this complication as the result of a virulent tuberculous infection. A predominance of small mononuclear cells is usual in tuberculous pleural effusions. It is not uncommon in effusions associated with neoplasms. It may occur in renal cases. Effusions in which coarsely granular eosinophilic cells are found in large numbers are probably not tuberculous. Basophilic cells occur rarely, and only in small numbers. On theoretical grounds it seems better to reserve paracentesis for the relief of urgent symptoms. In the analysis of this series of cases no clear evidence is obtained either in favor of or against paracentesis.

Torsion of Appendix.—When Bevers first saw this patient, she was suffering from abdominal pain and vomiting; sixty hours before admission she was seized with severe pain in the right iliac fossa during the night and vomited almost at once. The pain increased in severity and vomiting continued at intervals. On admission her pulse was 120 and her temperature 100 F.; the abdomen was slightly distended and generally rigid, this rigidity being most marked over the lower half of the right rectus, and there was acute tenderness on pressure in the right iliac fossa. Bevers regarded the case as one of acute appendicitis with perforation, and operation was at once undertaken. The appendix was found hanging over the brim of the pelvis; both it and the meso-appendix were much swollen and dark purple in color, and in places becoming black. At the base of the appendix and close to the cecum were two complete twists, there were no adhesions, and the appendix was quite free in the peritoneal cavity. The appendix was removed and the abdomen closed without drainage, recovery being uneventful. The appendix was 3 inches long, in a condition of acute gangrene, and contained a small concretion near the tip.

Juvenile Tabes.—Kerr's patient was only 14 years of age. The three striking features of the case: (1) lightning pains, (2) primary optic atrophy, (3) absent knee jerks, established the diagnosis of juvenile tabes in spite of the absence of a history pointing to hereditary syphilis and of the negative blood and cerebrospinal fluid Wassermann.

*Subconjunctival Lipoma. Cabannes and Dupérier.—p. 86.

Anatomy of Veins in Leg. G. Jeanneney.—p. 87.

*Medical Inspection in Schools. Gèzes.—p. 89.

Diphtheria Mortality.—Dubourg and Guénard review the experiences with diphtheria at the Children's Hospital at Bordeaux during the last thirty years. The mortality was 54 per cent. in 1888, but the annual average after antitoxin was introduced has been 7.28 per cent., with a minimum of 1.53 per cent. of 195 cases in 1907.

Subconjunctival Lipoma.—The fibrolipoma described was removed from the conjunctiva in the outer portion of the inferior culdesac of a healthy woman of 29. The tumor had been first noticed two months before.

Necessity for Examination of Ear and Nose in Medical Inspection of Schools.—Gèzes found in 117 children of the upper school grades at Bordeaux that over 42 per cent. had spurs on the nasal septum. Over 36 per cent. had coryza with hypertrophy; 56.4 per cent. had chronic otitis media, and 12.8 per cent. cicatricial otitis, in addition to the over 34 per cent. with enlarged tonsils and the 35.9 per cent. with adenoids.

Electrocardiography and Roentgenoscopy of the Hearts of Eight Athletes. J. Chuzet.—p. 540.

*Precautions in Radiotherapy. M. L. Gunther.—p. 544.

Electric and Roentgen Treatment of Sciatica.—Zimmern assumes that true sciatica can be traced to irritation or compression of the roots of the nerve, not severe enough to arrest the motor impulse. It may be amenable to direct irradiation or to indirect revulsion by a faradic or high frequency current or jet of hot air. Other physical measures seem to have only a symptomatic action. His experience warns against trying to combine roentgen-ray treatment with electric revulsion; the latter seems to undo the effect of the former. He usually gives 2 H units at a sitting. Relief may be obtained at the very first, but the second or third is generally followed by the subsidence of all the pain. Sometimes there is an exacerbation of the pain the evening or the day following each sitting. This exacerbation always proved a sign of favorable omen. If three sittings do not accomplish the result, he waits eight or ten days, to save the skin, and then repeats the course with doses of 3 instead of 2 H. The Achilles tendon reflex seldom returns, or not until very late.

Precautions in Roentgen-Ray Work.—Gunther is the director of an establishment for manufacture of electric and radiologic apparatus and devices, and he gives a long list of special precautions to be observed by the radiologist, for himself and for the patient, to avert immediate and tardy injury.

*Fibrotuberculoma in the Larynx. G. Portmann.—p. 101.

*Quantitative Test for Albumin in the Urine. L. Dupuy.—p. 104.

*Gas Cysts in the Abdomen. C. Lenormant.—p. 104.

Laryngeal Fibrotuberculoma.—Portmann was able to watch through several years the evolution of a fibrous tuberculous tumor in the larynx. It had been mistaken for cancer at first, and the larynx was exposed for laryngectomy. The tissues around were found infiltrated and thickened, so the proposed operation was abandoned, and the patient has been in fairly good health during the three years since he has been wearing his tracheal tube.

Albumin Test.—Dupuy compares the turbidity of a standard solution of albumin with that of the urine being examined after each has been treated with Esbach's citric-picric acid reagent.

Gas Cysts of the Abdomen.—Lenormant analyzes twelve recent (since 1910) works on the subject of cystic pneumatoses. It was recently discussed editorially in *THE JOURNAL*, March 13, p. 739.

*Inaugural Lecture of Parasitology Course. E. Brumpt.—p. 121.

Efficacy of Sodium Taurocholate as Local Preventive of Gonorrhea. L. Cheinisse.—p. 127.

Parasitology.—In the course of this inaugural lecture, Brumpt remarks that although the most common species of our parasites were known to the ancient Egyptians, yet there is nothing to show that the forbidding of the eating of pork by certain religions had anything to do with the danger of disease therefrom. He cites S. Reinach to the effect that nowhere in the Bible is there any reference to disease attributed to food, and that the idea of hygiene was born in Grecian civilization. The Abyssinians to this day, Brumpt says, do not eat pork or elephant meat, but they eat beef raw. He asked an Abyssinian chief the reason for this and for circumcision, and the reply was that both were done because their ancestors had taught them to do so, and because the mutilations "distinguished them from other people who, keeping as God made them, were like animals." Brumpt thinks that this, and not hygiene, is the key to the problem. In parasitology, as well as in surgery, Paré was a pioneer, with his advice to boil meat. F. Redi, in the seventeenth century, showed the origin of maggots from flies and of itch from an acarus, but the medicine of that day paid no heed to their discoveries.

*Revision in Workmen's Compensation. F. de Quervain.—p. 101.

*The Leukocyte Blood Picture in the Mountains. E. Ruppner.—p. 105.

*The South Wind and Pathology. K. Helly.—p. 108.

*Fatal Infection with Mouse Typhus. H. Staub.—p. 114.

Revision of Workmen's Compensation.—The Swiss law provides for a pension allowing revision during the first three years and again at the end of the sixth and the ninth years. De Quervain discusses the workings of the law in concrete examples. Among 94 cases of traumatic arthritis reexamined later, 38.9 per cent. of the supposedly disabled had regained their earning capacity; the figure was 55.8 per cent. among those cases dating from 1906 and 1907. On the other hand, in 4.2 per cent. of the reexamined, arthritis had developed as a tardy complication of the trauma.

The Leukocyte Picture in the Mountains.—Ruppner's investigation of 100 healthy persons showed a special leukocyte picture in the Engadine and at still higher levels (1,750 meters and 2,250 meters). The total number of leukocytes was normal or below, keeping at the lowest range of normal, as a rule, while the number of lymphocytes was above the normal figure, and of neutrophils was below. The proportion of mononuclears was somewhat above normal. His research demonstrated further that persons coming to the mountains generally displayed a pronounced leukocytosis at first—an acclimatation leukocytosis, as it were, which yielded in about six weeks to the mountain leukocyte picture as above. He remarks on the scanty literature on the leukocyte picture at high altitudes when so much has been written on the erythrocytes and hemoglobin changes.

The South Wind and Pathology.—Helly has been impressed with the wave of pathologic conditions which often pre-

cedes and accompanies a period of strong southerly winds. The number of deaths is higher, especially among persons with damaged hearts, and in those of unstable constitution, the thymicolymphatic status, as evidenced in the increased number of deaths under anesthetics, from myasthenia or in various diseases, the weather evidently depressing the resisting forces. The number of suicides also increases, and the number of accidents. The muscular, nervous and mental systems seem to be depressed, their vitality lowered, and physicians and surgeons should bear this in mind during the periods of strong southerly winds. Helly refers to the southerly wind called the sirocco in Italy and the föhn in Switzerland, and says that for fifteen years he has been studying its influence on the morbidity and mortality of the most varied classes of people and over a broad range of latitude, from Naples to Berlin, and found the evidences of its influence both in the living and at necropsies. Many persons feel the influence two or three days before the sirocco arrives, and are depressed and irritable.

Fatal Case of Mouse Typhus.—The previously healthy man of 62 ate five pieces of potato which had been spread with mouse virus to kill mice in the barn, made with *Bacillus typhi-murium*. He developed a fulminating infection which proved fatal in five days. There was no fever at any time, but the course corresponded to the cholera-resembling form of paratyphoid B.

- Pleural Effusion with Heart Disease. M. Lombardo.—p. 190.

The Thyroid and Infections.—Barbàra ascribes an important rôle to the thyroid in the struggle against infection. His experiments showed that after thyroidectomy some of the factors in immunization notably declined, including the complement, bacteriolysins, opsonic power and phagocytosis, but no modification in the antitoxin content could be detected after thyroidectomy. This lowering of the defensive forces rendered the thyroidectomized animals more susceptible to infections. The changes in the thyroid with acute and chronic infection readily explain certain symptoms observed in infections. The clinic and experimental pathologic physiology thus supplement and confirm each other. This opens a field for research on the effect of thyroid treatment on the serologic and cellular defensive forces in the course of infections.

Treatment of Pulmonary Tuberculosis.—Among the other measures applied at the Ferrarotto public sanatorium, artificial pneumothorax was induced in 56 patients and all were improved except 5 in whom conditions remained stationary, and 5 others in whom the disease progressed; 5 may be considered clinically cured and 15 immeasurably improved. In a previous series of 15 cases in which the course was concluded by 1912, all are in good condition still with the exception of 3; the marked improvement in these had persisted for two years, but their symptoms returned, and 2 have died.

Elimination and Retention of Urea.—Among the points brought out by Venza in this study of the present status of

this subject, is that he often found patches of apparently normal tissue in kidneys which at first glance seemed to be totally pathologic. Sometimes these normal areas gave evidence of compensative hypertrophy. He tried to estimate this reserve capacity of the kidney by comparing the urea content of the urine before and after test ingestion of 20 gm. of urea. The increase ranged from 1 to 18 gm. but the findings did not correspond to the known condition of the kidneys. Those showing the largest increase were not those with the mildest kidney disease, and repetition of the test gave variable findings. He emphasizes further that little reliance can be placed on the concentration of the urine from day to day. The maximal concentration is said to be more instructive, that is, the highest concentration in which the special substance can be eliminated. This is determined from the total urine for three or four days. It is said to be peculiar to the individual and constant in him. But in Venza's cases this maximal concentration was not constant. It seemed as if the urea had acquired a threshold below which its elimination was impossible. The kidneys seemed to be unable to respond to slight stimuli; only powerful ones affected them, and not always proportionately to the stimulus. This may be the reason why the Ambard ureosecretory constant is not always a reliable guide. The authorities even differ as to the normal standard, Ambard changing his early figure of 0.040 to a range from 0.065 to 0.070, and Weill accepts a range from 0.063 to 0.080 and, in the elderly, from 0.097 to 0.1. Raimoldi states that the normal limit is 0.080. In Venza's cases the constant was always above normal but not often proportionally to the severity of the disease, and it varied from time to time. In one patient it was 0.5 on two occasions and then 0.146, and in another 0.875, 0.633 and finally, as death approached, 0.328. The azotemia kept constantly high throughout, and the urea content of the urine did not change enough to justify this change in the Ambard constant. The azotemia in all his cases was constantly above 0.5 per thousand. An increase in the azotemia as edema subsides is always a grave sign, as the kidneys are unable to eliminate the urea which the edema fluid had been holding in solution. An increase in the azotemia as edema is forming shows the hampering of kidney function by the mechanical obstacle of the edema. The urea content of the blood with edema is therefore instructive, but only when the dilution is known. A few days of a diet to get rid of chlorids insure much greater precision. Five patients with azotemia above 2 or 3 per thousand soon died, and one with 1.70 per thousand did not survive more than a few months.

Factitious Conjunctivitis.—Borrello induced conjunctivitis in rabbits' eyes with castor-oil seeds and then obtained positive responses with an antiricin serum, with a diagnostic ricin collyrium, and with the deviation of complement test. With the latter it is a simple matter to detect factitious conjunctivitis induced with the seeds in man. The findings are illustrated.

Blue Disease.—Lombardo gives four pages of bibliography and the details of two cases in a man of 31 and a youth of 15.

Mediastinal Tumors.—Piazza-Martini reports twenty cases of mediastinal tumors causing unusual clinical manifestations. In some cases a frequent paroxysmal cough was the only symptom; it was worse on reclining, which suggested a movable tumor. In one case the symptoms indicated a tumor in the anterior mediastinum and it retrogressed in thirty-five days under sodium iodid, and all traces of it had disappeared by another month. There had been no need to apply the Wassermann test or radiocopy as improvement was so promptly evident under the specific treatment. In one case the tumor causing the cough was discovered when the reclining patient was drinking. The swallowing movements brought an accessory and enlarged thyroid, close to the isthmus, into view. It retrogressed to a clinical cure under iodids and there was no further coughing in any position. Paralysis of one vocal cord was the only symptom in one case from a clump of enlarged peribronchial glands. One woman of 50 developed symptoms testifying to compression of the azygos where it entered the vena cava, with dysphagia from engorgement of glands in the right posterior medias-

tinum. Under large doses of sodium iodid the symptoms rapidly retrogressed, although there was nothing to suggest syphilis. Emphysema, acute catarrhal bronchitis, or compression of the descending vena cava were the only symptoms in some other cases. No operation seems to have been attempted in any of the cases. All proved fatal except the few mentioned above.

Phenol Lipoids.—Piazza's experiments in chemotherapy have resulted, he says, in demonstrating peculiar properties in a combination of phenol and various lipoids, differing from the properties of either alone, and differing further according as the lipoids were derived from egg yolk, brain tissue, cholesterolin or lecithin, and with or without addition of camphor. Addition of 2 gm. of the phenol-cholesterin-camphor combination to 10 c.c. of tetanus toxin annulled the toxicity so that guinea-pigs bore without harm five times the lethal dose of the tetanus toxin thus treated. The bactericidal action was most pronounced with the Shiga dysentery bacillus, and least with the pneumococcus and streptococcus. No irritating nor analgesic action on the skin or mucosa could be discovered, even with prolonged contact.

Prophylaxis of Malaria. M. Rizzi.—p. 748.

Infectious Abortion in Horses. M. Carpano.—p. 752.

Municipal Prophylaxis of Malaria.—Rizzi relates experiences in Italy which demonstrated the advantages of keeping the domestic animals between the dwelling places and the pools or marshes that breed the mosquitoes, when it is impossible to keep the pools thoroughly oiled to destroy the larvae. At Trinitapoli, where malaria has long been prevalent, the stables and barnyards were removed outside the city limits and on the side toward the marshes. The stables swarmed with mosquitoes, and as they were killed off day by day, new hosts arrived, but the city escaped. No mosquitoes entered the city, and no new malaria cases developed, although the endemic was severe in the country around. The barns for the animals attract and collect the mosquitoes, and they can be destroyed readily while collected here, repeated attacks on them keeping the hosts under control. Roubaud in Paris has also recently called attention to this means of segregating the mosquitoes.

Infectious Abortion in Horses.—Carpano has isolated a bacterium of the paratyphoid group from mares with this disease and from the polyarthritides of the colts born from these mothers. It was frequently associated with a streptococcus, and he has reproduced with it a fatal disease in rabbits, guinea-pigs and dogs. It responds to agglutination tests. Characteristic cultures of both are shown in two plates.

Antiserum for Gas Gangrene.—Fasiani discusses the preparation and the action of immune serums against the anaerobes responsible for experimental gas gangrene.

Tuberculosis in Single Kidney.—Forni induced a tuberculous process in both kidneys and then removed one the fifteenth day in four guinea-pigs and slaughtered the animals the thirtieth day. The same procedure was applied to a series of eight rabbits. In a third series the interval before nephrectomy was two months and before killing three months. Some colored plates accompany the article. The data presented confirm the favorable effect on a tuberculous kidney of removal of its mate. The remaining kidney hypertrophies and it becomes functionally more capable. In animals, at

least, the tuberculous process is retarded and modified by processes of sclerosis which tend toward healing and to recovery.

Nov. 13, 1919, 40, No. 91

Lavage of Spinal Cavity in Epidemic Meningitis. C. B. Farmachidis. p. 988.

Rinsing Out the Spinal Cavity in Meningitis.—Farmachidis emphasizes the benefit in a case in which he rinsed out the spinal cavity with a 7.5 per thousand physiologic solution, using up to 360 c.c. at each sitting, and keeping this up daily for twenty-five days. He first withdrew 30 c.c. of the spinal fluid and then injected the same amount of the physiologic solution. After a minute or two this was then gently aspirated or allowed to flow out, and 30 c.c. were injected again, repeating this ten or twelve times at a sitting, thoroughly rinsing out the cerebrospinal canal, the fluid finally coming away clear. The procedure is not painful, but injection of antimeningococcus serum causes some pain. By the second application in the case described the fever disappeared, and the young man became conscious, while the procedure seemed harmless. The cerebrospinal fluid was clear by the twenty-third day. Aubertin reported in 1915 having treated fifty men with three injections of 50 c.c. of the antiserum, preceded by rinsing with a total of 150 c.c. of physiologic solution, and a cure followed.

Solid Hard Ovarian Tumor. E. Bussa-Lay.—p. 1.

Healing of Pseudotuberculous Peritonitis After War Wounds of Chest and Abdomen. G. Egidi.—p. 8.

Ether in Surgical Infections. G. Fantozzi.—p. 19. Contr.

Solid Ovarian Tumor.—The large tumor described by Bussa-Lay was so hard from infiltration with lime salts that knife and saw made scarcely any impression on it.

Ether in Surgical Infections.—In this instalment of Fantozzi's long report of research on this subject, he describes the results of flushing the peritoneal cavity of rabbits, guinea-pigs and dogs with ether, according to Morestin's technic, after inducing peritonitis. Other experimental work showed that ether has only very weak antiseptic properties. His experiences on the whole warn decidedly against the use of ether for rinsing out the diseased abdominal cavity. One special drawback is the intense cold which it induces. In abdominal operations it is one of the cardinal indications to keep the viscera warm. In some of the animals, even small amounts of ether induced hemorrhagic lesions in the viscera and degenerative changes in the kidneys, besides the active hemolytic property of the ether. When poured into the peritoneum and its evaporation prevented, all the animals died from shock. When the abdomen was left freely open, so the ether fumes and any excess of fluid could escape, two of the seven rabbits (15 to 50 c.c. ether) died, and two of the three guinea-pigs (20 to 30 c.c.). Only one survived of seven guinea-pigs given intraperitoneal injection of from 0.5 to 1 c.c. of ether, and four of seven rabbits. The guinea-pigs died in a few minutes, the rabbits not until the fifth and eighteenth days. The volatilized ether evidently paralyzed the respiration by reflex action from pressure on the diaphragm. Normal rabbits bore the ether with comparatively little disturbance. The report of his clinical experiences will form the next instalment of his article.

*Postdiphtheric Paralysis. L. Spolverini.—p. 617.

*Foot Phenomenon in Meningitis. A. Nizzoli.—p. 637.

Postdiphtheric Paralysis.—Spolverini queries whether the postdiphtheric flaccid condition of the muscles should properly be called paralysis, as the disturbances are more in the nature of myasthenia in the majority of cases and in four he describes here and compares with similar cases on record. In three of his cases the disturbances were arrested with antitoxin, and they retrogressed completely in from twenty to forty days. The larger the amount of antitoxin injected, the prompter the cure. In the fourth case the antitoxin had not been commenced until the twenty-seventh day, and only comparatively slight improvement was realized. These cases teach further the necessity for taking smears from the nose with postdiphtheric paralysis, as this may reveal virulent diphtheria bacilli. Some even assert that nasal diphtheria is more apt than other forms to be followed with paralysis.

The Foot Phenomenon in Meningitis.—Nizzoli cites conflicting evidence from various writers on the constancy and significance of the various signs of meningitis in children, of which he enumerates a long list. The excitability of the nervous system in children causes a host of symptoms which obscure the diagnosis. The signs which depend on reflex action are the most instructive in children, as they cannot fight against them. In two cases of tuberculous meningitis he noted dorsal flexion of the big toe and a fanlike spreading of the other toes when he tried to induce the identical contralateral reflex. The other leg became spontaneously flexed, and the toes assumed the position mentioned above. The reflex is induced on the recumbent child, with legs extended, by flexing one on the thigh and on the pelvis, with moderate compression, watching the behavior of the other leg. This foot phenomenon could never be elicited in healthy children, but could be induced at will in both these meningitic children. In others with the disease more advanced the response was negative, confirming that the phenomenon is an earlier sign.

January, 1920, 18, No. 1

*Progressive Muscular Atrophy. G. Fiore and G. Guidi.—p. 1.

Progressive Muscular Atrophy in Children.—Fiore and Guidi give nearly four pages of bibliography on progressive muscular atrophy or dystrophy of muscles, and two colored plates of the findings in one of their three cases in infants. The latter died from pneumonia at the fifth, seventh, or fourteenth month. The muscular atrophy had been noticed soon after birth, and displayed a rapidly progressive course, with lax paralysis. The children seemed otherwise normal. Two had the same parents; they were born about four years apart, and two other children in the family were said to have shown symptoms resembling these. Two other children in the family are normal and in good health. The pathologic anatomic findings in the third case demonstrate the existence of an intermediate form between the idiopathic and the spinal muscular atrophy type.

*Echinococcus Intradermal Reaction. A. Testi and C. Zoli.—p. 601.

Echinococcus Intradermal Reaction.—Testi and Zoli announce that when this intradermal test is negative, exploratory puncture is justified. But it should never be done when this test elicits a positive response, and this is the rule in echinococcus disease. The exceptions are rare. The test

is made by inoculating one arm with 0.5 c.c. of fluid from an echinococcus cyst on a guinea-pig or beef, drawn less than twenty-four hours before. A control inoculation is made with physiologic saline on the other arm. Long series of tests on other patients and on the healthy failed to elicit the slightest response, but in thirty patients with echinococcus disease the local reaction was unmistakable in both adults and children. In one child the test was negative until cyst fluid from a sheep was used. This elicited a typical reaction. The absence of the local reaction is a sign that either there is no echinococcus disease, or else that the products of the cocci have not sensitized the organism. In either event exploratory puncture is harmless. On the other hand, a positive reaction indicates a phase of sensitization in which exploratory puncture is liable to induce symptoms of serious anaphylaxis. In some cases a positive reaction could be elicited even years after operative cure of the cyst.

*Peruvian Pseudomolidae. E. Escomel.—p. 160.

The Anatomists of Peru. H. Valdizan.—p. 164.

Tuberculous Pneumonia.—Gonzalez reports a typical case of what he assumed to be chronic pneumonia of the fibroid hyperplasia type, for which attenuated tuberculous infection was probably responsible. The symptoms were those of lobar pneumonia, but there was a history of moderate hemoptysis twenty-five years before, with no other symptoms of tuberculous infection. The tubercle bacilli are seldom to be found in the sputum in such cases, but tuberculin-iodid treatment, begun the thirtieth day in his case, induced specific reactions, brought down the fever, the symptoms subsided, and the man of 54 has felt perfectly well during the four months since he left the hospital apparently cured by the tuberculin stimulating the production of antibodies.

Indigo in Ancient Peru.—Velasquez and Maldonado review the history of the use of indigo in America, many textiles, etc., dyed with indigo having been found in tombs from pre-Columbian days. They give an illustration of part of a garment dating from the Inca period, decorated with indelible blue figures.

The Pseudobeetles of Peru.—Escomel adds another to the list of eight pseudomolidae which have been described in Peru, five first by him. The blood of these insects seems to have been used from time immemorial to cure warts. The papilloma becomes blanched and looks as if it has been cauterized with a strong acid. The active principle has been identified with cantharidin.

*Gallbladders with Partitions and Gallstones. D. Prat.—p. 813.

Classification of Motor Disturbances: Hyperkinesia. A. Ricaldoni.—p. 842.

Suprarenal Insufficiency as Factor in Psychoses.—Rossi has encountered nine cases in which a manic-depressive psychosis developed during the weakness following influenza. He ascribes it to the suprarenal insufficiency which was manifest. This assumption was confirmed by evidences of suprarenal insufficiency in six other patients with manic-depressive

psychoses who had not had influenza. It was placed on a still more solid basis by the efficacy of suprarenal treatment. The beneficial action of epinephrin in these cases seems to lift the veil of mystery from the manic-depressive psychoses, and expose their origin and means to treat them.

Partitions in Gallbladders.—In one of the cases illustrated, constriction of the walls of the gallbladder, at about the lower third, had imprisoned a large gallstone; in another case two were imprisoned by an hour-glass constriction. In others the gallstones were lodged in a diverticulum, or a fibrous septum had walled off part of the gallbladder and with it a stone. In one case the gallbladder had bent double, shutting off communication between the two halves. This partitioning off of the gallbladder may be of inflammatory origin, or from deformity from the weight of stones, or from a tumor nearby, or from some mechanical valve formation. If we bear the possibility of such anomalies in mind, we will not waste so much time waiting for spontaneous expulsion of the calculi which is absolutely impossible in these conditions.

- *Glycogen in the Auriculoventricular System. P. Rojas.—p. 192.

Technic for Suturing the Intestine.—Perera presents thirty-nine illustrations of the various steps of suturing a perforation and of anastomosis, with comment based on his personal series of fifty-eight cases.

Hyperthyroidism and Pseudohysteria.—Juarros declares that every day he encounters more and more persons whose disturbances have been ascribed to hysteria with the consequent therapeutic indifference, when in reality closer study of the case reveals excessive functioning of the thyroid as a factor. This hyperthyroidism can be easily cured or at least much attenuated, he continues, when the thyroid symptoms are discovered, tremor, sweating and mononucleosis, besides the usual triad of tachycardia, palpitations and the ocular signs. The tremor is rendered evident by having the patient extend his arms and hands, spreading the fingers. A sheet of paper laid on the hand renders plainly manifest any tendency to tremor. Hysteria can be excluded by the mentality, the hysteric character being easily recognized, so that, he says, "there is no excuse for labeling as hysteria every feminine neurotic manifestation." The instability of the thyroid may induce attacks of hyperthyroidism which may simulate in every respect the phases of a neurosis with the arthritic constitution. The excessive thyroid functioning may even entail obsessions, phobias, hallucinations and delirium, still further confusing the diagnosis. He has recently seen a case with the set of symptoms described by Block in 1912, and it yielded to antithyroid treatment. The patients in this category are usually old maids, and pigmentation is a characteristic symptom, most marked in the muscles, cheeks and side of the brow. They are self-centered, melancholy and irritable, complain of fatigue and insomnia, and are doomed to suffer incurably so long as hysteria is regarded as responsible. A prompt cure in all these hyperthyroid cases may usually be realized under antithyroid plus ovarian treatment, with calcium salts and sodium cacodylate as adjuvants. The main thing is to give adequate doses and persevere long enough.

Renal Lipomatosis.—Serés' patient was a woman of 26; during convalescence from influenza constant pain developed in the left kidney and the urine was turbid, but there were no other signs suggesting a tuberculous process. The pains grew so severe that the kidney was removed, and it was

found full of fat, the soft yellow fat having taken the place of the true kidney tissue, only a narrow shell of the latter being left. In the three analogous cases on record the patients soon died, as also Serés' patient but in none was the kidney process directly responsible for the death. Serés' patient succumbed to pleurisy a month after the operation.

Glycogen in Auriculoventricular Conducting System.—Rojas reports as the results of extensive microscopic and chemical research on the impulse-conducting system of the heart, that there seems to be a larger proportion of glycogen in the tissues here than elsewhere.

Genito-Urinary Fistulas.—Werneck had five women with these fistulas in his service during a recent two months. He describes the various operative measures applied, and compares them with others in the literature, giving thirty-one illustrations. In some of his cases labor had lasted from three to eight days; in one of these a calculus in the bladder had been a factor, and a pessary in others. In conclusion he says to emulate Sims' pertinacity, and keep on operating anew, undaunted by apparent failures, until finally the fistula is conquered.

Revista Medico-Cirurgica do Brazil, Rio de Janeiro

September, 1920, 27, No. 9

*Fulminating Otogenous Meningitis. F. Eiras.—p. 319.

Fulminating Otogenous Meningitis.—Eiras' 14 cases confirm the frequency of meningitis from this cause, and the danger of its nonrecognition. In one case a physician had been unjustly arraigned, and the day he should have appeared in court he died suddenly. No one knew he was sick, but necropsy revealed meningitis from catarrhal otitis. The course of the meningitis had been so fulminating that the death had been ascribed to suicide. In the 3 fatal cases in Eiras' practice, 2 of the patients had changed doctors because he had insisted on an operation, and the third consented to intervention only when practically moribund. Two of the 6 successful operative cases were in infants of 4 and 11 months. In one young adult the meningitis was consecutive to gonococemic otitis, mastoiditis and arthritis of the temporo-maxillary articulation, and the operative measures were supplemented with vaccine therapy according to Wright's method. A cure was realized without operation in 5 cases, draining the suppurating otitis media and rinsing with hydrogen dioxide once or twice a day; these were all children but one. The otitis had developed during convalescence from influenza in 3 of them. Even a simple catarrhal otitis is liable to set up meningitis. There had been no pus in the discharge from the ear in one of his cases, but the operation disclosed a large collection of pus. This frequent finding sustains the theory that otitis media is not always due to invasion from the nasopharynx but may be a local explosion from a general infection. This mechanism was evident in his gonococemia case; there was no suppuration in the middle ear, but it contained the gonococcus. The mastoid antrum should be opened up at the slightest suspicion of involvement of the brain. We must remember, he says, that the most treacherous cases may show very few symptoms, and that an exploratory operation here is the most harmless of all surgical ventures. During the 1917 epidemic of acute otitis media he often encountered 2 or 3 or even 6 cases in one home.

Twin Pregnancy with Placenta Praevia, etc. L. Huguet.—p. 569.
Paratyphoid plus Colon Bacillus Fever. M. A. de Villiers.—p. 572.

Brush Treatment of Trachoma.—Guiral has applied with good results Howley's aspirating cannula for treatment of trachoma but this does not scrape off the sago-like elevations so perfectly as a dentist's circular brush run by an electric motor. The small, narrow, rapidly revolving brush sweeps off the granulations without the slightest harm to the mucosa. The surgeon thus realizes more than he can ever obtain with the vacuum cannula or other means, he says, while the conjunctiva is left as smooth and clean as if there had been no granular disease. He applies it under ether, and compresses the lid at the operation to expel the blood somewhat. After thus sweeping the conjunctiva clean, he applies the vacuum cannula to aspirate all secretions, blood, etc. Several stereoscopic views accompany the article.

Glaucoma.—Guiral describes the technic for Elliot's method of treating glaucoma, and declares that it is superior for all forms of glaucoma. He has recently had to apply it to six young persons under 20, all belonging to two families in which the parents and grandparents had required treatment for acute glaucoma. The young people had simple glaucoma; the rapid decline of vision was arrested by the Elliot operation, and vision is now excellent.

*Colloidal Gold Reaction in Body Fluids. H. Iida and S. Tominaga.—p. 217.
*Banti's Disease. T. Mitamura.—p. 245.

Colloidal Gold Test of Body Fluids.—Iida and Tominaga have been studying the colloidal gold reaction in the cerebrospinal fluid, in effusions and exudates and in urine, milk and bile, and its relations with the Wassermann, Nonne and other reactions, in health and in pathologic conditions. Their charts and the tabulated comparative findings in fifty-one cases show parallel reactions as a rule with the first phase of the Nonne reaction and pleocytosis, but the colloidal gold reaction was sometimes negative when the Wassermann was positive, and vice versa. Scarcely any of the exudates induced the maximum precipitation below a dilution of 1:10,240, but with transudates the range was wider. The reaction indicates that there are three kinds of transudates. With one the maximum of precipitation is between 1:10 and 1:320; with the second kind, between 1:940 and 1:1,280, and with the third, at 1:2,560. No difference between the urine from sound and diseased kidneys could be detected. Precipitation occurred with human milk, blister fluid and bile. They warn that in preparing the colloidal gold, the vessel must not be covered, as retention of the gas generated interferes with the reaction later. They specify a few other minor points in the technic.

Revision of Banti's Disease.—Mitamura presents evidence that the spleen in true Banti's disease shows fibroid degeneration of spleen tissue while the liver may in time develop cirrhosis or atrophy, but it differs essentially from that with Laennec's and other forms of cirrhosis. He cites 141 articles on the subject from the literature, and gives five plates of photomicrographs of the necropsy findings in seven cases reported with minute detail. There was a history of syphilis in two, and it was suspected in a third case. He declares that the term Banti's disease should be restricted to this type of primary splenomegaly with gradually increasing simple anemia, with finally, sometimes, ascites, and in the later stages gastro-intestinal hemorrhage. Splenic anemia and Banti's disease are therefore synonymous terms, he adds. The latter is essentially much like hemolytic jaundice, especially the acquired form, although not exactly the same. Thrombosis in the portal system is mainly responsible for the late ascites in the Banti's syndrome. In Mitamura's cases the enlargement of the liver was noted under 10, under 20, or under 30 years of age in about half the cases, and this stage of splenic anemia lasted from a few years to twenty years. Then the stage of ascites without impairment of the bile

secretion lasted about a year. In the third, terminal, stage the liver was much reduced in size and bile production was diminished. This phase lasted two or three years. No operation had been attempted except in two of the cases; fatal peritonitis followed in one, and the other patient succumbed to heart weakness. The others died in time from marasmus or gastro-intestinal hemorrhage.

- Morphology of Lymphocytes. H. Klien.—p. 1117.

Prohibition of Exhibitions of Hypnotism.—Schultze deplors that hypnotic exhibitions are becoming so frequent, as he has seen great harm result to subjects who have been hypnotized. He recites in detail the case of a young woman who after being hypnotized one evening by a traveling hypnotist presented marked mental disturbances. As she started for home, she insisted that she must go back, again and again, and at home she ran about with fixed eyes and outstretched hands, apparently insensible to her surroundings, though she recognized her friends. The hypnotist was finally sent for at a late hour, and he succeeded in quieting her. After a restless night she went to her work, but was unable to attend to her duties and had to be sent home. She felt compelled to return to the hypnotist, and complained that she could not think clearly. After a week of this, Schultze hypnotized her in presence of a colleague, and impressed on her that in future only Schultze and his assistant could hypnotize her, and that after this she would have no more trouble. She was then very slowly and cautiously brought out of the hypnotic state and in a few days had entirely recovered. He emphasizes that hypnosis cautiously applied is the best means to cure the effects of hypnotism improperly carried out. Before the war, some of the German states had laws prohibiting exhibitions of hypnotism, but they are not being enforced now. Austria and Italy have also passed laws of the kind.

The Sachs-Georgi Reaction.—Wollenstein and his associates made comparative tests by the Sachs-Georgi and the Wassermann methods in 1,000 cases, from which, it seems, four conclusions may be drawn: 1. Even with the most careful technic, misleading results seem bound to arise on account of the seemingly unavoidable errors in preparing the solutions, and it is therefore important always to use more than one type of reaction, in order by comparing results to reduce the percentage of error to a minimum. 2. The Sachs-Georgi reaction becomes manifest in syphilis earlier and may be elicited later than the Wassermann reaction. 3. The number of unspecific Sachs-Georgi reactions is relatively high, being especially common with *ulcus molle* and in febrile conditions. Clinically healthy subjects may for the time being give positive Sachs-Georgi reactions. 4. The foregoing observations limit materially the usefulness of the Sachs-Georgi reaction as compared with the Wassermann reaction. A diagnosis of syphilis and conclusions as to continuing treatment can therefore not be based entirely on a positive Sachs-Georgi reaction, nor even on a series of positive reactions.

Treatment of Leukemia with Deep Roentgenotherapy.—Two years ago Rosenthal published a preliminary report of his treatment of leukemia with deep roentgenotherapy. His experience at that time had been that after only one sitting the number of leukocytes was reduced to normal in from ten to fourteen days, during which time the spleen had become much smaller. The subjective symptoms disappeared in cases in which other therapeutic methods had failed. He gives in detail the history of his oldest case: The white cell count varied from 250,000 to 300,000. Feb. 5, 1917, the patient received a deep roentgen-ray treatment. February 14 the white cell count was 30,000, and later went down still further and remained under 50,000 until the end of April, 1917. End of October the white cell count was back to 250,000 again. The patient returned and received another single treatment. The count fell by crisis to 5,000 and remained stationary for

several weeks, but by June, 1918, after gradually rising, it had reached 230,000 again. A third treatment brought the count promptly down to from 5,000 to 10,000, but by January, 1919, it had again reached 230,000. After a fourth treatment the count was 20,000. The spleen decreased in size after each treatment. For five or six months after each treatment the patient felt well and was able to work, but then a slight weakness set in, with a feeling of pressure in the region of the spleen; these symptoms were promptly relieved by renewed treatment. Rosenthal's experience thus indicates that the favorable effect of a deep roentgen-ray exposure wears off in about eight months, when treatment must be renewed. He still considers this the most reliable treatment in leukemia. Severe reactions, however, do result, and he admits a mortality of 12 per cent. in 25 cases, which he considers a fair showing in view of the seriousness of the prognosis in leukemia.

- *Fat in Plastic Operations on Lungs. K. Stromeyer.—p. 420.

Prolapse of the Rectum.—Heinemann advocates a method of operative treatment with which he has been successful in nearly all of twenty-six exceptionally severe cases. He sutures the anus, and then through a median incision, from the anus to the coccyx, with a semicircular extension at the edge of the anus, he slits the muscles and loosens up the rectum walls. Then he passes three threads lengthwise through the rectum wall, except for the mucosa. As the threads are tied, they take up three deep transverse folds in the rectal wall. By tying the ends of the threads from each side together, a lengthwise fold is taken up also. The higher threads are fastened to the coccyx or a ligament to suspend the rectum. The levator ani muscles are then sutured, and if necessary a fold is also taken up in the sphincter.

Arterioesenteric Duodenal Ileus.—Ranzel cites experiences which demonstrate that this form of strangulation ileus can develop without dilation of the stomach, contrary to the opinion of some. He then reports a personal case in which a much emaciated man of 28 developed the arterioesenteric duodenal occlusion spontaneously. The symptoms came on suddenly while he was traveling, obliged to stand up, and he had been eating very little. There was no collapse, the colic-like pains being the main symptom. When he reclined, the pains were relieved. In this case and in four others on record there was bluish discoloration below the occlusion. In treatment, the knee-elbow posture should be tried, introducing the stomach tube with the head low. If these measures fail, he advises gastro-enterostomy before the debility becomes extreme, as he applied in his case, with prompt recovery.

Congenital Clefts in the Face.—The cleft in the face extended from both orbits to the mouth, the nose region forming thus a peninsula, as it were, and the umbilical cord was firmly impacted in the cleft, while an amniotic band was caught in one orbit.

Fat in Plastic Operation on Lung.—Stromeyer says that the cavity in the lung left from a war wound was large enough to hold two billiard balls, several ribs having been resected and three fistulas from the bronchi opening into it. He twisted a pedunculated flap of adipose tissue around to fill the defect, with a second flap to hold it in place. The bleeding and the coughing stopped at once, and recovery was soon complete except that the man still has to wear a corset to prevent the flapping of the lower part of the chest wall on that side.

Utilization of Capillary Attraction to Differentiate Typhoid and Colon Bacilli.—Friedberger dips strips of filter paper, 1 cm. wide and 10 cm. long, for twenty seconds to the same depth in equally concentrated suspensions of typhoid and colon bacilli. After the fluid has mounted up the strips by capillary attraction, the strips are then pressed down side by side for a moment on Endo plates. As the cultures develop it is found that the typhoid bacilli have mounted higher, as a rule, than the colon bacilli. The experiment may be made with a mixture of the typhoid and colon bacilli, and the strips may be cut into pieces 1 cm. wide (as far as the fluid has climbed). If these pieces are then put in a physiologic sodium chlorid solution and cultures made on Endo plates, the colon bacillus cultures will be found almost exclusively on the lower portions of the strips. The higher on the strips, the more the cultures of *B. typhosus* predominate. He is continuing his research on this elective capillary attraction for different bacteria, and thinks that it will aid materially in differentiation of the various types.

Surgical Wound Diphtheria.—Kehl states that in order to pronounce a final diagnosis of wound diphtheria, examination of smears alone is not sufficient, as it is impossible to determine to what extent pseudodiphtheria bacilli may be mixed with the genuine bacilli. He therefore recommends that in all cases in which pole-staining bacilli are isolated, the final diagnosis should be made on the basis of animal inoculation. An accurate diagnosis is especially important in view of the fact that genuine wound diphtheria is just as infectious as pharyngeal diphtheria. Sixty wounds that looked suspicious were examined as to their *B. diphtheriae* content and found to be negative. There was one finding that seemed doubtful, but inoculation of an animal showed that the organisms were pseudodiphtheria bacilli.

Instrument for Recording Intrathoracic Pressure and the Respiratory Mechanism.—Drachter describes a syringe instrument which serves to give a clear idea of intrathoracic pressure relations under physiologic and pathologic conditions.

Deep Thermometry.—Zondek gives a series of tables illustrating the varying temperature found in different parts of the body. The temperature in the musculature of the abdominal walls and the extremities is lower than that of the rectum, but near large blood vessels the temperature of the muscles is slightly higher, although still lower than the rectal temperature. The differences are not constant, and vary in different subjects. The temperature of the tissues gradually diminishes toward the surface of the body. Each centimeter marks a difference of 0.25 C. on an average. Layers of fat are poor conductors of heat and serve as a protection in the heat economy, consequently a dry skin presents a lower subcutaneous temperature than an oily skin. If the skin is oily, there is thus a marked contrast between the epidermis and the underlying fascia. The temperature of subcutaneous tissues depends on the character of the underlying tissues, being lowest over bones. The temperature of organs, taken during operations, showed that the liver, the kidney and the uterus had temperatures between the preoperative and post-operative rectal temperatures. During the operation, the body temperature falls. The lungs have almost rectal temperature, the difference being 0.2 C. In one suppurating uterine myoma the temperature exceeded the rectal temperature, doubtless owing to acute inflammatory phenomena. In a hydrocele a surprisingly low temperature was noted.

Diagnosis of Tuberculous Meningitis in Children.—Rominger comments on the tendency to regard tuberculous menin-

gitis as a distinct disease, whereas it is important to bear in mind that it is in reality only one aspect of general miliary tuberculosis, and that the condition of the other organs, especially the lungs, may offer valuable evidence for an early diagnosis. Although tuberculous meningitis is usually easily recognized if there are pronounced brain symptoms, yet in the beginning of the disease, as long as only dubious general nerve symptoms are present, diagnosis is often difficult. Even when meningitis is diagnosed, it is often difficult to ascertain what form of meningitis is present. Roentgenograms of the lungs should be made, and they are often valuable, especially if the lungs already show signs of miliary tubercles, but negative results do not by any means exclude tuberculous meningitis, as miliary tubercles in the lungs often develop late, sometimes only shortly before death. Lumbar puncture is instructive. The tubercle bacillus is found only in from 80 to 90 per cent. of the cases and often requires several days of patient search. Lymphocytosis can only be regarded as a possible indication. Increased pressure as shown by lumbar puncture is important, but more valuable still is evidence of an increased albumin content of the cerebrospinal fluid, for which Pandy's reaction is the most reliable and practical method. This consists in adding a drop of cerebrospinal fluid to 1 c.mm. of 7 per cent. phenol solution. Cloudiness at the zone of contact is a sign that the fluid contains easily precipitable albuminous substances in pathologic quantities. In a series of fifteen cases the Pandy reaction was positive.

- Treatment of Malaria. W. Brandt.—p. 475.
- *After-Treatment of Dislocation of the Hip Joint. G. Müller.—p. 479.

The Predisposition to Accidents.—Widmer argues that the inbred experience of countless ages enables us to sidestep injury unconsciously. Only when we focus our consciousness on the reaction to the occurrence is injury liable to result. By practice or by diverting the attention, the consciousness of the act becomes eliminated, and the inbred experience then carries us safely past the danger point. He refers in particular to industrial accidents.

Treatment of After-Effects of Pleurisy, etc.—Zadek gives case histories which show the remarkable benefit that can be derived from the special breathing exercises he describes in warding off and curing adhesions and many chronic pathologic conditions entailing retraction and shriveling of lungs and pleura. Inspiration is slow and deep "as if to burst one's belt"; expiration is aided with the hands applied to the chest wall below the breast, the thumb turned toward the back, the little finger on the costal arch at the nipple line, the fingers in the interspaces. There should be no active pressure from the hands. Inspiration should take about four seconds and expiration three seconds, and the exercise should be repeated from three to six times a day. Three inspirations at first are enough, but later from three to eight minutes or longer are given to the exercise. The exercise should always stop short of inducing palpitation, etc.

After Correction of Dislocation of the Hip Joint.—Müller applies a splint or other appliance after correction which relieves the hip joint of weight bearing, while at the same time it presses the head against the acetabulum. As the hip joint is used, the head bores a niche for itself. By this prophylactic treatment in all cases in which conditions seemed to invite recurrence, it has been ward off except in

two of his hundreds of cases in the last fifteen years, and in these two there had been fracture of the neck.

Plastic Operation on Under Lid for Support of Artificial Eye. H. Teske.—p. 128.

Avoidable Cause of Psendarthrosis.—Katzenstein relates experiences which apparently demonstrate that the capacity of the bone marrow for regeneration of bone is sufficient for the healing of a fracture but that if any periosteum tissue is in contact with the bone marrow, the regenerating capacity of the latter is modified. Instead of producing bone, only a bone-like cartilage is produced. The result is a psendarthrosis instead of normal healing. In experiments on animals, the bones could be made to heal normally or develop psendarthrosis at will, by preventing or allowing any contact between periosteum and bone marrow.

Case of Bilateral Tubal Pregnancy. H. Brossmann.—p. 174.

Fatalities After Sacral Anesthesia.—Zweifel analyzes the ten fatalities that have been published as following sacral anesthesia, among the 4,200 cases on record in which this technic has been applied. In only three of the total ten fatal cases could the sacral anesthesia be held responsible. In these cases death followed in a few seconds, in seven minutes or in ten minutes, evidently from acute procain poisoning. In all the cases, 0.6 gm. of procain was the smallest dose used, and in some it was up to 0.9 gm. No mishaps have been recorded with doses of 0.4 or 0.5 gm.

Treatment of Eclampsia and Hyperemesis.—Hofbauer presents a number of arguments that the pituitary and suprarenal glands play an important part in the pathogenesis of pregnancy disturbances. The brain, liver, kidneys, and stomach are affected by the hormones from these two glands, and in ovarian treatment we have a means to inhibit the action of the pituitary and suprarenals on the sympathetic nervous system. By this antagonistic organotherapy he thinks we now have a specific causal means of treatment. Cases of severe hyperemesis at the second month and of eclampsia at the ninth month in two primiparas treated in this way with ovarian extract showed marked benefit. This treatment seems to paralyze the pathogenic excessive functioning of the pituitary-suprarenal system. He advises to give the ovarian extract early and freely, from the first symptoms, with sedatives, but strictly avoiding morphin and pituitary extract. He warns also against chloral for more than a single dose of 2 gm., by the rectum, saying that chloral injures the heart, and its action on the respiratory centers also calls for extreme caution. It may induce cyanosis and pulmonary edema.

*Medicine in Europe a Hundred Years Ago. H. T. Deelman and C. C. Delprat.—p. 1.

Medicine a Hundred Years Ago.—Three young physicians started from Holland to visit the medical centers in France

and Germany in 1818. One was C. B. Tilanus, and Deelman and Delprat have compiled an account of the medicine of that day from their diaries and notebooks, particularly those kept by Tilanus. Dupuytren and Larrey at Paris seem to have shone by their kidney stone, hernia and fracture operations, but abdominal surgery was practically unknown. Only one of the mastectomies for cancer proved successful among the many they witnessed. All the other patients succumbed to infection. Only one survived of ten women operated on by Dupuytren for cancer of the cervix, and he knew of only one woman still living two years after an operation of the kind.

*The Diagnosis of Exophthalmic Goiter. A. Troell.—p. 33.

*Lumbar Puncture in Treatment of Acute Wood Alcohol Poisoning. M. Zethelius.—p. 45.

Hypersensitiveness to Epinephrin in Hyperthyroidism.—Troell gives charts showing the clinical response to subcutaneous injection of 0.5 c.c. of a 1:1,000 solution of epinephrin in six patients with manifest exophthalmic goiter and in four with ordinary goiter. The findings on the whole confirm those reported by Goetsch (1918) in 195 cases of goiter, including fifty of the exophthalmic type, demonstrating the peculiar hypersusceptibility to suprarenal extract in clinical states of hyperthyroidism. This characteristic response to epinephrin and also the discovery of extreme functional activity of the thyroid cells, as indicated by the mitochondria contents, will aid in the differential diagnosis from other nervous disturbances, and also in estimation of the value of different modes of treatment. The surgeon also may be interested in the peculiar hypersensitiveness to epinephrin with hyperthyroidism, as affecting his routine use of epinephrin with the anesthetic at operations.

Lumbar Puncture in Treatment of Blindness from Wood Alcohol Poisoning.—Zethelius gives here a preliminary communication on the benefit from lumbar puncture as he witnessed it in three cases of blindness from methyl alcohol poisoning. Great improvement in vision followed the lumbar puncture at once and continued to progress, as the punctures were repeated, in one case, with vision up to 1 in about a month. There had been an interval of four days before any appreciable symptoms had developed, and then all the symptoms except the visual soon subsided. In the second case the punctures were begun the second day after ingestion of the liquor, with vision of 0.1/60 in the right eye and only perception in the left. The amaurosis persisted for twelve days but by the end of the second month vision had become 3/50 and 0.1. In the third patient, vision increased from amaurosis by the tenth day to 0.3/60 and 1.5/50 in about seven weeks. In these last two cases there was persisting atrophy of both papillas. The lumbar puncture was repeated three or four times in each case. The benefit from it, Zethelius says, surpassed that from any other known method of treatment. We know that alcohol or its derivatives pass into the cerebrospinal fluid; they have been found in it at necropsy in wood alcohol cases, and release of the toxic fluid is thus directly indicated, while reduction of intracranial pressure may lessen to some extent the chance for absorption by the nerve substance of the poison in the fluid.

THE SOMATIC CAUSES OF PSYCHONEUROSES *

CHARLES L. DANA, M.D.

Professor of Nervous Diseases, Cornell University Medical College
NEW YORK

Wandering through a bookshop some months ago, I saw two counters piled up with literature devoted to varieties of psychic experience and elucidation. There were books on new thought, on dreams, on personality, on the disadvantage of being inferior, on pschanalysis (adapted to any intelligence), on psychic research; also on slips of the tongue, Christian science and the life beyond. It showed to me what a tremendous grip the psyche had taken on the unthinking but reading world. I still like the soul and follow its aspirations, but I feel as if the psyche was overworking her job and becoming psychopathic. Perhaps this experience had something to do with the trend of this contribution, which is an effort to show that there is a physical, a neuropathic factor in the causation of the psychoneuroses; also that the psychoneuroses may develop directly from concussions, traumatisms and toxins, and that some constitutional neuropathic condition is necessary for the psyche to work out its mechanisms of defense, readjustment, etc.

THE EMPHASIS PLACED ON PSYCHOGENESIS

The psychoneuroses are the so-called functional troubles which are grouped more specifically under the heads of hysteria, psychasthenia (compulsions, obsessions, fears), neurasthenia and anxiety states. Among these groups, the war neuroses were made up largely of hysterias and anxiety states, while in nontraumatic civil life we find a greater prevalence of psychasthenia and anxiety states.

There has been a tremendous amount of emphasis laid on the psychology and psychogenesis of these affections. The formula that war neuroses, taking them all in all, were nothing more than defense states, namely, the expression of a subconscious desire through awkwardly planned devices to get away from the front, was almost officially promulgated.

On the other hand, among the internists, there has been a large amount of activity of thought and emotion paid to the physical side of these conditions. Autotoxemia and sepsis dominate a field once occupied by malaria, the reflexes and other vague phases of pathogenesis. There is at present a sort of rivalry between the colon and the teeth, on the one hand, and the gonads and the psyche on the other. I do not attach myself to either of these groups, but I find that

there are always physical as well as psychic factors in the causation of the psychoneuroses; that pathologic reactions do not occur in anatomically and physiologically sound bodies.

DENIAL OF EXISTENCE OF FUNCTIONAL DISEASES

I do not suppose that any one denies now that there is really no such thing as a functional disease. In all the neuroses and psychoneuroses something material and neural has happened. To say, then, that a disorder is due to emotion or to some prompting of the subconscious or to a suggestion, is not giving the last word of explanation. There is some evidence that we can have no emotion without a previous physical change, and it is definitely known that emotion is always associated with and followed by notable physical changes. The neurotic disorders, such as hemiplegia or monoplegia, which follow an emotion have, one may be sure, also some underlying physical change. It seems to have been lately demonstrated that these physical changes which are usually associated with an emotion may also occur as the result of concussion or toxemia. In other words, psychoneuroses are not ever entirely psychogenic, but are sometimes somatogenic and sometimes of mixed origin.

Carver and Dinsley¹ state that there is a large group of war neuroses in which the causative factor is not emotional, but commotional. This commotional group of neuroses is composed of three subgroups: (1) one in which there is direct concussion by the missile on the tissues, overlying the nervous system, but no damage to brain, cord or membranes; (2) a subgroup in which there is no direct concussion but the patient is subjected to violent variations of pressure from proximity to the explosion, and (3) a subgroup in which the factor is extremely rapid vibrations which are one of the less known products of the detonation of high explosives. The vibrations are capable of agitating the nervous system in such a way as to produce a condition which clinically closely resembles that produced by emotion.²

Carver and Dinsley performed experiments on animals. They established a detonating station, X, and arranged a series of three zones about it. Zone A included the area of direct concussion; Zone B that of indirect concussion, and Zone C, an area in which high explosives detonate only if they have the same tonal standard as the explosion at X. They also experimented with fish and then with rats and mice.

1. Carver, Alfred, and Dinsley, A.: Some Biological Effects Due to High Explosives, *Brain* 42:113 (June) 1919.

2. Carver and Dinsley give some interesting facts about explosives. The pressure of high explosives may exceed 300 tons per square inch, and the waves of detonation run through the exploding mass at the rate of 10,000 meters per second. As the result of an explosion, there occur massive vibrations due to compression and decompression, molecular vibrations, and probably finer ethereal vibrations, such as are utilized in wireless telegraphy.

Finally, they made observations on men working in a demolition station and subjected to the effects of detonations but protected from any direct concussion and not subject to any element of fear. They found that in zones B and C fish lost for hours their sense of equilibrium; that in these zones rats and mice showed forms of paralysis and nervous disturbances, from which they eventually recovered, and that in zones B and C some of the men showed marked nervous disturbances.

They conclude that (1) while the neuroses of war may be and are brought on by purely emotional shock, the importance of this has been overestimated; (2) they may be caused also by "purely physical shock" as demonstrated in their experiments, or (3) they may be of mixed origin.

CLINICAL EVIDENCE

Clinical evidence of some physical and physiologic defects in the genesis of many psychoneuroses is very abundant. I have many recorded cases, but I shall refer to only one.

A boy, aged 19, whose family history was good so far as nervous or mental disorders were concerned, whose father died of hemorrhagic pancreatitis, and whose mother and a sister were living and well, when young had been well and normal, good at school and social in his habits, with some musical taste and talent. At the age of 14, while going to school, a boy said to him: "What is that on your ear?" This annoyed him and he felt as if there was something in the ear, and became nervous about it. Next day while going to school, he suddenly felt as if there were a burning torturing fluid in his head and pouring through his body. The sensation lasted only a moment, but immediately afterward he became very nervous, restless and apprehensive. He was afraid especially of having another seizure, etc., and did not dare to go to school. Then he became afraid to go out alone on the street and was in constant apprehension lest something would happen to him. The range of his fears enlarged; he feared he might have tuberculosis or paralysis, or some other disease. He had finally to give up all his school work, and he was placed under a private tutor. Finally he became too nervous to pursue his studies under any conditions.

In the first year of his illness, he had two or three more of these "seizures" followed by increase of nervousness. No attack was as severe as the first, however, and in none of them was there any fainting or twitching or palpitation. His family noted no physical change during the attack, though he thinks he became pale.

When 16 years old, his father secured a farm and put him to work on it. He tried this for a couple of years, but got no better and finally gave it up and came home. He was then 18 years old. One afternoon he went out with his father to see a fire. He used to love to go to fires, but at this one he became frightened and had another seizure. After this he was worse than ever. The sound of fire-bells threw him into hysterical excitement, and he would tremble and cry. He became afraid even of the sound of trolley cars. He could not go out of the house alone, he was afraid to meet people, and was continually running to his mother, telling her his troubles and asking for relief. His father meanwhile had died (which relieves us of considering the so-called Oedipus complex).

During all this time his symptoms were combated by his family and physician, by change of occupation and environment, therapeutic talks, sedative medicines, etc.

He was brought to me a short time after the fire episode, when he was at his worst. He had then been for four years nervous, apprehensive, hysterical and entirely lacking in courage, independence and capacity to concentrate or carry on any kind of study or work.

I was told that his habits were good, and there was no history or evidence of masturbation—a matter closely

inquired into. His physician thought he had deficient sexual activity. He slept badly, but he had no fear dreams except once—just after the first attack.

I found him to be an intelligent boy, affectionate, unselfish and very anxious to get well, and tremendously disturbed by his nervous condition. He showed no objective signs of nervous disease, nor any of the stigmas of dementia praecox. His story was not of the schizophrenic type.

The boy was 6 feet, 2 inches in height, but he had no marked pituitary anomaly. He had no signs of thyroidism except a slight tremor of the hands. His hair and teeth were normal. He had not the make-up of status thymolymphaticus; his hands and feet were often cold and blue; he had undue fatigability and indefinite myalgic pains, a constant subnormal temperature and a dry skin. The blood pressure was normal. He was not anemic.

He was placed on 5 grains of thyroid gland twice a day; later, 2 grains twice daily.

Within two weeks after treatment was begun, the boy was rather magically changed. He lost his fears and restlessness, and nervousness and insomnia. He was able to go out alone.

He went back to his farm, worked there daily, motored, and became practically well and continued so for nearly three years. He takes the thyroid intermittently, and if he feels nervous or panicky, he gets relief after using the gland.

Recently I had a letter from him saying he was practically well, though he occasionally got a little nervous and apprehensive.

Nov. 10, 1919, he came to my office and confirmed the foregoing story.

He described again his seizures. Suddenly, without any cause except perhaps some extra excitement, he felt as though a burning, torturing fluid were filling his head and body. He became pale; his hands sweat. The sensation left him at once, and sometimes he immediately felt normal. Then in two or three days, there came on him a condition of nervousness and apprehension, and he passed into a chronic condition of an anxiety neurosis, with restlessness and insomnia, and constant fears of a return of the seizure, or some other disaster.

This patient is not cured, and he may have some recurrence of his condition. I do not infer from this isolated case that psychasthenic conditions are always or even often due to hypothyroidism. I do not know even now that it was hypothyroidism in this case or that there was not other endocrine defects, and that thyroid feeding simply reestablished a balance.

There must have been behind his gland defect some instability of the nervous centers. There always is in these cases. But the case does demonstrate that sometimes a gland defect is present in the psychoses and that no amount of attention paid to mental conflicts, conversions, condensations, complexes, sense of inferiority or any other phases of the psychoanalytic and therapeutic effort would be of much use as long as his internal secretions were working defectively.³

The facts I have recited I am sure sufficiently emphasize the points: I have wished to make and I might end my paper here.

But I would like to say something about the particular physical changes that occur, I believe, in part or in whole in the psychoneuroses.

THE SOMATIC MACHINE

We are told that these disorders are essentially bred by emotion; but from this point on, the method of development of the psychosis is different in accordance with the school of psychology to which one belongs.

We know, but perhaps we do not always realize, how intricate and delicate is the physical machinery

3. Dr. Beverley Tucker has reported three cases similar to the foregoing. Compare also Wechsler, I. S.: *Neur. Bull.*, 1919, No. 2.

connected with emotional states and the mental processes. We know the location in the brain of parts concerned in sensation, perception and memory; we know that the mental machine is made up functionally of many complex minor systems, and that consciousness is associated with the coordinated activity of a large portion of them. We know that the parts hang together by reason of very numerous tenuous threads and delicate contacts.

THE SYNAPSIS

An explanation of certain brain functions has been based on the hypothesis of the activity of the dendrites, and their ameiboid movements. This view has been put forth by Mathias Duval and Lépine. It has been supported by Wiederham and half a dozen others. It has been contradicted by the experiments of Azoulay and others. Lugaro has another theory; that of the turgescence and subsidence of the cell body and dendrites. Renaut has a somewhat similar view, and for a time Cajal invoked the movements of neuroglia. Later Cajal argues that new paths of psychic activity may be created by the growth and exercise of the fibrillae and dendritic processes, and weakened by disease and decay of these organs. Sherrington lays especial emphasis on the functional importance of the synapsis.⁴

All these views came to the same point, namely, that the paths of conduction in the brain may be blocked or made more free by physical and mental agencies, and that in the activities of life there are continual shiftings and realinements.

I am going to venture on some speculations connected with these known anatomic facts. There is no reason why theorizing should be confined to psychologic machinists. And, besides, what I advance is not without some laboratory support.

It may be assumed that since the synapsis is a point at which the traveling nerve impulse has to pass over a break in anatomic continuity, it here meets its highest resistance. Some neural phenomena, therefore, might be expected to develop here, just as light or heat develops when an electric current meets a specially great resistance. The synapses of the cerebral cortex are thought to be the seat of consciousness (Macdonald). Whether this is so or not, I only use the term synapsis as symbolic of the fact that there are breakable points and points of variable resistance in the finer organizations of the brain.

The neural basis of disorders of association, such as occur in retardation, and of blocking of thought and of flight of ideas, may be in part explained by this mechanism.

Hysteria is a disease characterized by a dissociation of psychic systems functioning in sensation, perception or thought.

It is probable that the other psychoneuroses, neurasthenia, psychasthenia and the anxiety states, are due to dissociation of systems of neurons.⁵

4. Very early in evolution, we find that this mode of connection ceases and the cells, now known as "neurons," although in functional continuity, are separated from each other at the "synapse" by a membrane which plays a very important part in the mechanism of the reactions which take place in nerve centers. . . . The phenomena of fatigue, summation, irreciprocal conduction, excitation and inhibition are connected with this membrane (Bayliss: Principles of General Physiology, pp. 474, 477).

5. This view was given and elaborated on in the last edition of my textbook (1915); and Dr. Boris Sidis has independently worked out the same hypothesis, that the anatomic seat of the psychoneuroses is in the synapses, or due to their disturbed functioning. Experience confirms me in the opinion that this is a good working theory.

Recent experiments have given some laboratory proof of this kind of reasoning.

A. R. Moore⁶ has shown that strychnin, which greatly increases the reflex excitability of animals with a synaptic nervous system, has no effect on the neuro-molecular system of coelenterates which have no synaptic elements. It has a slight influence on echinoderms and a much greater one on crustaceans and mollusks which have more developed nervous systems.

Such a view, namely, the blocking of a functionally similar group of neurons or a decrease in its resistance, seems also to explain therapeutic results. In certain forms of psychasthenia with an underlying fatigue state, strychnin or small doses of opium will in a short time clear the mind and entirely relieve the patient. In some cases of very marked obsessions and anxiety and fears, feeding with pituitary and thyroid extracts promptly changes the whole character of the patients. A young man with an obstinate psychoneurosis was always promptly relieved by the administration of the "panacea" of Antonius Muca, the formula for which I obtained from Galen's works.

The morbid somnolence of dyspituitarism, due perhaps to some synaptic block in the thalamic region, has been relieved by gland feeding (Niles).

We know that the seat of the mental activities is not so much in the cell as in the conducting fibrillae, and it is these that are most disturbed in functional psychoses. The functions of the cerebral nerve cell are trophic and perhaps mnemonic.

The cell rapidly deteriorates and changes its content and form, but the nerve fibers are practically unfatigable, although they have as active metabolism as that of gray matter. These fibers are so persistently active because they are supplied with nourishment as well as with protection by the medullary sheath, except at the dendritic and peripheral endings; so we ought to expect exhaustion at the synaptic points sooner than in the cell or in the nerve itself. They would be also more exposed to the influences of toxins and fatigue products.

When a person has a great emotional shock, and there follow tremors, speech defects, paralyzes or anesthesias, it may well be because the synapses of certain groups of neurons functionally selected and embryologically of similar development are blocked by the torrent of impulses aroused by fright or pain combined with excess of epinephrin or other toxic material thrown into the blood. Certain parts of the nervous centers are specially sensitive to infections and poisons, as shown in the case of encephalitis lethargica. The Lange-James theory of emotion and the physiologic experiments of others indicate that some physical change takes place in the nervous system which produces or precedes the mental state. In other words, the elaborate psychologic mechanism of the psychoneuroses with its theories of conflict, repression, conversions, compromise formations, condensation-inversion, uncompensated feeling of inferiority, may exist, but all these are not always necessary, and they are always agencies which have to act through a neural mechanism. If this is sound we shall rarely if ever get any psychosis.

The cause of psychoneuroses is not altogether a repressed sexual wish, an uncompensated feeling of inferiority, the basic emotional state of fear, the unsuccessful subconscious conflict, the Oedipus complex, or

the image-parent, if the whole thing disappears under pluriglandular feeding, nux vomica or codein. Yet I have seen all these things occur sometimes.

It is probable that very many kinds of conscious and subconscious mental disturbances, bad mental habits, misuse and misdirection of normal instincts as well as colonic and dental toxemias may lead to the same interference with the function of synaptic groups.

In the higher processes of mental activity there is an increased number of association-activities, and a greater danger of interference at these sensitive points.

In a motor-act, the nerve impulse passes through only two or three neurons. In a simple sensation, the impulse passes through four or five neurons. But in the mental state associated with fear and shock, with its aroused associated memories, the number of neurons and synapses involved is immensely greater and more widely diffused.

We know that in persons who are subject to psychoneuroses there is a congenital or acquired special instability of the nerve centers, including those of the sympathetic and autonomic nervous system. This means, for one thing, that there is a weakness or defect in association and consequently a defect in those associations which give control and balance, the processes of deliberate thought and judgment.

When a slight emotional shock throws a person into morbid panic or tears, it is because some of the associative strands that ordinarily feed into the conscious mind do not act. Some synapses are blocked; some are spastic and overtight in their connections.

There is reason to believe that we can at times control these synaptic functions by force of will—if one chooses to use that now tabued word—or by changing the field of attention. We raise the threshold of consciousness in our intentness and we no longer hear annoying sounds. By training, we prepare the brain and mind against painful impacts. Some persons can lie down and so direct their attention that they put themselves to sleep in a few minutes. We certainly, directly or indirectly, hold much control over the dendrites, if they are healthy. So I am supposing that in psychoneuroses, a sick synopsis may be the factor on which the activities, aroused by some emotion, or by the vibration of Zone C play, and thus, by attacking it, we get all the clinical phenomena of these disorders.

THE MECHANISM OF SOMATIC ORIGIN OF PSYCHONEUROSES

When an emotional state, say of fear, exists, I suppose that vibratory waves and auditory sensations have produced neural changes associated with an intense consciousness of fear, and then perhaps there follows unconsciousness. Many physical changes, vasomotor, glandular, etc., occur at the same time. If this condition now is followed by a hemiplegia or stuttering and tremor, I contend that these latter conditions may be due to subtle changes in the nervous systems. Cellular swelling, varicosity of the dendrites, blocking of synapses, or neuroglia movements. I would add focal injury with diaschisis; for the principle of diaschisis may play a part in minor as well as major local injuries.

The other view, which also may be true, is that after the detonation or concussion and emotion a certain subconscious psychic power is exercised by which the patient determines that he shall tremble and stutter or be hemiplegic or blind in order to accomplish a certain

object. This is to assume that some kind of conscious or subconscious force like that of a "censor" loosens certain inhibitions, or sends out or checks a certain intelligently directed morbid neural discharge.

This view is an interesting and plausible hypothesis. I put the matter somewhat like this:

X is the center of detonating force; Zone A, of direct concussion; Zone B, of indirect concussion; Zone C, of indirect concussion by high frequency waves.

The patient in B or C receives and feels:

1. Concussion waves on the brain and hears
2. The detonation.
3. Physical changes occur in the nervous system due to concussion with gross, or fine, or molecular waves.
4. Emotion, e. g., of fear, leading to Nos. 6 and 7.
5. Subconscious desires, defense activities, adjustment activities leading to No. 7.
6. Organic or biochemical disturbances in the nervous system (toxic or endocrinic, leading to No. 7).
7. Psychoneurotic phenomena.

What is claimed by me and shown by experiment is, that Nos. 4 and 5 may not be present and are not always causative factors; also, that in the nontraumatic psychoneuroses, such as the psychasthenias, neurasthenias and anxiety states, Nos. 4 and 6 are dominant, acting on a neuropathic nervous system. This particular form of the neurosis is determined by the special structural weaknesses in the individual's make-up.

REPLY TO OBJECTIONS

Of course, the first and obvious retort to the view I am supporting is this: If a monoplegia, for example, or other form of neurosis has an organic cause, how can it be cured by a single mental effort or by suggestion?

My reply is that the organic change is in more than a majority of cases biochemical, yet real as a sclerosis, brought on by a shifting of neural changes through attention or concentration on a certain object.

In certain emotional and exhaustion states the stomach does not secrete juice, and in the same way the neurons do not transmit their currents. In emotional states the total of neural or cerebral energies is massed in certain minor and major association groups connected with the particular form of apprehension or terror. By effort of volition or by a counteremotion, the equilibrium is restored. But some patients do not get well by any of these easy methods.

The sacred formula of dynamic psychology is that mental activity is a biologic phenomenon—to which we gasp and assent. Every action of the mind must be preceded by a previous action, every thought by some previous mental state. Hence it is said, we can trace back the cause and mechanism of all mental states by sufficient analysis. This view, however, is not proved and is, indeed, proved untrue. Certain mental states may be caused by concussion or by toxins.

CONCLUSION

My argument, then, is to the effect that the psychoneuroses are organic as well as psychic conditions. Being thus in part neurologic diseases, I think it would be a disaster if neurology were to abandon the study of this exceedingly numerous and sorely handicapped group of patients. If this should happen, they would go first perhaps to various types of psychotherapeutic specialists and perhaps later to clinical psychologists

and pedagogues. The last is already happening. The management of these cases calls for the closest observation and the most accurate study of the personality, but also of physical, metabolic and endocrine defects. It is, therefore, to trained neurologists conscious of their responsibilities and familiar with the best technical methods that the care, and I would add the prevention, of psychoneuroses belongs.

53 West Fifty-Third Street.

THE PHYSICIAN AND PROHIBITION

BERNARD FANTUS, M.S., M.D.

Associate Professor of Therapeutics, Rush Medical College
CHICAGO

The question now before us is not whether prohibition of the use of intoxicating liquors as beverages is right or wrong—though most of us are convinced that it is one of the most beneficent acts ever passed by a legislature—but, it being the law of the land, how we can aid in its enforcement not merely passively, by obeying the rules and regulations formulated by the authorities, but actively as well by devising ways and means of making easier the establishment of the new order. As the medical and pharmaceutic uses of alcohol offer, at present, some of the most perplexing problems in the administration of prohibition, it behooves us to formulate principles for guidance in our use of alcoholic liquids, most especially to determine to what extent we can dispense with the use of wine, whisky and brandy: for although alcohol prescribed under any other name is just as intoxicating—when it is less pleasant, it is less liable to cause addiction, especially when safeguarded by the regulations of the prohibition law.

USE AS SOLVENT AND VEHICLE

The employment of alcohol as a solvent, vehicle and preservative would be much reduced, and, with this, the chances of the abuse of medicines as intoxicating liquors greatly diminished, if some of the principles here outlined were incorporated in practice.

The solid form should be preferred to liquid medication, not only for this but also for other reasons. Solid medicine is smaller in bulk, and hence more portable. This is the reason traveling men often request that their medicine be prescribed in capsules. Disguising is much more readily accomplished, especially by encapsulation. In view of the fact that, for instance, the horrible taste of the iron, quinin and strychnin combination can be completely disguised by prescribing it in the form of capsules, it is poor technic, to say the least, to inflict the elixir "I. Q. and S." on a patient's palate. Danger from incompatibilities, as, for example, from formation of a poisonous sediment, is also done away with by prescribing in solid form. Furthermore, dosage is more accurate, as variations in the size of teaspoonfuls is eliminated. The chief reason for administration in liquid form is the necessity of minimizing gastric irritation by such agents as soluble iodids, bromids, salicylates or chloral.

The popularity of proprietary medicines, it has well been said, is directly proportionate to the amount of alcohol they contain and the inoffensiveness of their other ingredients. A principle which, it seems, if incorporated in legal regulations regarding proprietary

medicines might save the authorities much difficulty in eliminating the use of these nostrums as intoxicating beverages is this: Proprietary medicines must be put up in solid dosage form, unless the dry residue is so highly irritant as to be injurious to the stomach when given in this manner. Thus, the generally specious claim of the necessity of alcohol as a solvent and "preservative" might be done away with, and the use of these tipples ended. It will then be found that, for many proprietary medicines, alcohol was indeed the essential preservative of popularity.

In case of extractive preparations, the coming pharmacopeial revision might do away with tinctures of harmless drugs. The fluidextract of such drugs, being much more concentrated and active, is less likely to be used as a beverage. With poisonous drugs, on the other hand, there is no danger of their tinctures being put to such use.

The entire class of spirits, with the exceptions of the aromatic spirit of ammonia, the spirit of nitrous ether and the spirit of nitroglycerin—all of which are sufficiently medicated—might be deleted from the pharmacopeia, if formulas were devised for flavoring emulsions to take the place of the flavoring spirits. In point of fact, spirit of peppermint or other volatile oil containing spirits, when employed as carminatives or as flavors, are always used in the form of an emulsion, that is, the spirit added to an aqueous medium. Then why not dispense these oils in the emulsified form, which would detract naught from their medical or flavoring value, and eliminate their spirits from the list of possible intoxicants? Spirit of ether, spirit of chloroform and spirit of camphor, being simple, easily prepared solutions, are as superfluous in the pharmacopeia as would be aqueous solutions of iodid or of bromid.

As aromatic elixir is useful for the administration of alcohol-soluble drugs, it might be retained in the pharmacopeia. Until medicated, it is properly classed as an intoxicating beverage and subject to the regulations governing the sale of these. The elixir of glycyrrhiza, being merely aromatic elixir with the addition of 12.5 per cent. of fluidextract of glycyrrhiza, ought to be deleted. The aqueous elixir of glycyrrhiza of the National Formulary, being a valuable vehicle of very low alcohol percentage (4.5 per cent.), might, with advantage, be introduced into the pharmacopeia in its stead. Many of the feebly medicated elixirs of the National Formulary might well be deleted, especially if an "equalalcoholic vehicle elixir" were introduced, that is, one whose alcohol percentage would be subject to adjustment by the pharmacist so as to make it equal to the strength of the menstruum used in the preparation of the tincture or fluidextract, for which the elixir is employed as a vehicle. The physician cannot possibly be asked to carry in his mind the strength of all the various menstrua; and, if the alcohol percentage is not correct, a turbid liquid is the result liable to dangerous sedimentation. The pharmacist, on the other hand, with the aid of a tabulation, could readily adjust the vehicle to the medicament. This new "equalalcoholic vehicle elixir" might even take the place of the aromatic elixir, now official.

EXTERNAL USES

When alcohol is wanted as a disinfectant, the addition of 1 per cent. or more of iodine, phenol, cresol, or formaldehyd renders it, at one and the same time, more

efficient as a germicide and unfit for use as a beverage. Especially should the addition of iodine to alcohol increase its utility, when it is used for the production of hyperemia as well as for its disinfectant value under an occlusive dressing in the treatment of felons, boils and other subcutaneous inflammations. When, on the other hand, rubefaction is not desired, as in the treatment of infectious dermatoses, then the addition of boric acid to saturation (5 per cent.) cannot but enhance the antiseptic action. The same thing is true of its use in chronic otorrhea. In both conditions, the alcohol is to be used in as great a concentration as can be tolerated—from 25 to 95 per cent. When the astringent action of alcohol is chiefly aimed at, as when it is used for a backrub in a bed patient, a saturated solution of alum in diluted alcohol is preferable to plain alcohol. For antipyretic sponging of the fever patient, the use of alcohol is entirely unnecessary. Cool water will do as well and is much cheaper.

It is only when alcohol is to be used in the mouth as an astringent and possibly as a disinfectant that palatability must not be lost sight of. Even then the lotion may be made much more efficient as well as unsuitable as a tippie by synergistic additions, as for instance in the following prescription, which yields a mouth disinfectant, if such a thing is possible.

	Gm. or C.c.
R Phenyl salicylate	1.0
Menthol	1.0
Methyl salicylate	1.0
Alcohol	75.0
Water	to make 100.0
Mix. Label: Teaspoonful to tablespoonful as mouth wash.	

This may be used without dilution or diluted with water, according to the potency of the effect desired.

INTERNAL USES

When pure reflex stimulation of the heart and the blood vessels is aimed at, the aromatic spirit of ammonia is as efficient, though not as pleasant to take, as whisky or brandy. If narcotic effect is required, in addition, as in the treatment of shock, the admixture of ether (up to 30 per cent.) makes alcohol at least as efficient as when it is given in the form of whisky or brandy and probably more efficient. It is, however, chiefly because of its value in gastric and other colics, that such solution has earned the name of "anodyne" ("Hoffman's Anodyne"). The diaphoretic and diuretic value of alcohol is enhanced by the presence of nitrous ether in the spirit of nitrous ether, which therefore ought to be superior to whisky for "breaking up a cold."

When desired for its stomachic action, whisky or brandy might find in an aromatic fluidextract of gentian a less intoxicant succedaneum. When wanted for its food value in a fever patient, alcohol in pure form, properly diluted as in milk punch—a teaspoonful to a tablespoonful per cup of milk—may be prescribed, though, of course, whisky or brandy might be employed here, if desired. Prohibition has done nothing to interfere with the use of these; it has merely surrounded it with certain formalities to safeguard the patient against the danger of becoming an addict.

PHARMACOPEIAL RECOGNITION

An attempt will be made, perhaps without any sinister motive whatever, to restore wine, whisky and brandy to the pharmacopeia. This would be a move in the wrong direction. The most that can be said for those liquors is that they are pleasant administration

forms for alcohol. However, their very pleasantness has endowed them with such seductiveness and destructiveness that they have become outlaws among us. To restore them to the pharmacopeia would be heralded by the liquor interests as an indication that alcoholic beverages are wholesome and important medicaments, indispensable in medical practice and that the medical profession is now acknowledging the mistake it made regarding them. Prohibition, as now constituted, would be distorted into the appearance of a medical monopoly. "Why should the ordinary man," people would be asked, "have to pay for a medical consultation every time he wants a little whisky to cure a common cold?" "If liquor is a good tonic for the sick, why should it not be a good energizer for the well?" Such and other considerations might start a political landslide into the wet abyss.

In point of fact, as has just been shown, whisky and brandy are entirely unnecessary in medical practice. Quite a number of hospitals of Chicago, such as the Presbyterian Hospital and the Cook County Hospital, as well as, of course, the Frances Willard Hospital, do not dispense any of these liquors; and yet their patients, so far as is known, are none the worse for it. As alcohol is the main active principle of the ardent spirits and of practically equivalent therapeutic activity, why burden the pharmacopeia with them? We might as well introduce pyroligneous acid, coal tar and crude petroleum, because it is claimed by some that these native mixtures have a therapeutic value superior to any one of their pure active principles. And, if we were to introduce whisky and brandy, why stop there? Why not also introduce into the pharmacopeia a dry white and red wine, port or sherry, gin and champagne, beer and stout, each of which has, under certain circumstances, special therapeutic virtues perhaps not possessed to the same extent by alcohol. The chief plea that can be made in favor of the reintroduction of liquors into the pharmacopeia is that, now that they are recognized as medicines, a standard for them is required. This standard may, however, just as well and much better be furnished by the authorities entrusted with the enforcement of the prohibition act.

CONCLUSIONS

The medical profession has every reason to welcome the advent of prohibition. It will protect the physician from the danger of causing inebriety in a case in which the patient might be benefited by the medicinal use of alcohol.

For most purposes for which alcohol is required in treatment, it may with advantage be medicated so as to render it unfit for use as a beverage.

The therapeutic employment of liquor, especially in the form of wine, whisky or brandy, ought to be minimized, so as to eliminate the possibility or even the suspicion of abuse. The authorities entrusted with the enforcement of the prohibition law ought, therefore, to have no difficulty in distinguishing between the *bona fide* and the *mala fide* prescriber of alcoholics.

Good Health and Good Government.—Good health and good government are the two essentials of a great and permanent civilization. These conditions are reciprocal and complementary. Neither can exist without the other.—W. S. Rankin, *Tr. Assn. Life Ins. Presidents*, 1919.

TYPHOID FEVER IN THE AMERICAN
EXPEDITIONARY FORCESA CLINICAL STUDY OF THREE HUNDRED AND
SEVENTY-THREE CASES

VICTOR CLARENCE VAUGHAN, Jr., M.D.

Major, M. C., U. S. Army

DETROIT

(Concluded from page 1081)

THE PARATYPHOIDS

In the Allied armies the paratyphoid fevers have played the dominant rôle, while the typhoid bacillus itself has caused only a small proportion of cases. In contrast, the American Expeditionary Forces have had a comparatively insignificant number of the former. With our total of 270 cases of straight typhoid we have had reported to us only twenty-three cases of paratyphoid B and nine of paratyphoid A, with an additional twelve classed as paratyphoid fever, indeterminate. Reports of foreign observers are concerned chiefly with studies of paratyphoid infections in the straight typhoid vaccinated, and the consensus is that this type of vaccination exerts no protective influence against the paratyphoid organisms.

TABLE 7.—INCIDENCE AND AVERAGE DAY OF APPEARANCE
OF SYMPTOMS AND FREQUENT COMPLICATIONS IN
TWENTY-THREE CASES OF PROVED
PARATYPHOID B.

Symptom	Cases in Which Symptom Was Present, per Cent.	Average Day of Disease on Which It Appeared
Constipation.....	21.7	1.0
Anorexia.....	73.9	1.7
Malaise.....	65.1	1.7
Headache.....	47.8	1.7
Chill.....	39.1	2.4
Diarrhea.....	65.2	3.0
Vomiting.....	21.7	4.0
Bronchitis.....	52.2	4.1
Average date of admission.....	...	4.5
Hemorrhage.....	4.3	5.0
Bronchopneumonia.....	4.3	5.0
Abdominal pain and tenderness.....	42.4	6.6

Delirium.....	13.0	16.0
Average length of fever.....	...	25.6
Relapse.....	4.3	32.0
Mortality.....	4.3	...

Close study of the symptomatology among our cases of paratyphoid (Tables 7 and 8) have led us to these conclusions:

1. On the whole, the disease follows a much milder course than does the eberthian infection. The mortality, as contrasted with 11 per cent. in the latter, is 4.3 per cent. in paratyphoid B and 0 per cent. among our nine cases of paratyphoid A.

2. An individual case cannot be distinguished by its clinical characteristics from straight typhoid. Diarrhea occurred in a slightly larger proportion, but so also did initial constipation. The date of onset of diarrhea was, on the average, a little earlier. Rose spots and palpable spleen were not found as frequently. Relapses did occur, and the fever stopped at about the same day in all three types.

3. The only means of definite differentiation in the individual case is that of bacteriologic identification.

I have not presented the symptomatology in paratyphoid A and B infections graphically as I regard the number of cases too small for reliable statistics.

White blood counts plotted according to the day of disease as for the straight typhoid cases showed in general a higher count, which averaged, for the entire period, 10,000 in the paratyphoid B and 9,000 in the paratyphoid A cases.

CLINICAL TYPHOID FEVER

In addition to those classified as infected with one of the organisms of the typhoid-paratyphoid group, we have had fifty-nine cases presenting strong clinical evidence of typhoid fever, but in which the organism was not demonstrated either in the blood or in the stools. This number does not include all cases reported to the chief surgeon as clinical typhoid, as many did not show conclusive enough findings to warrant the diagnosis. The criteria for acceptance into this group were: (1) presence of rose spots and palpable spleen; (2) presence of either one together with a definite leukopenia and a clear history of a continued fever for two or more weeks, or (3) as in one instance, a continued fever of four weeks without rose spots or palpable spleen and without leukocytosis, but with intestinal hemorrhage occurring in the second week.

Tabulation of the symptomatology among these cases gives results quite similar to those of straight typhoid. The incidence of rose spots and palpable spleen is higher; but this is due to the fact that these signs were usually required for acceptance into the group. The logical explanation for the occurrence of these cases would be that bacteriologic examinations were not made often enough, and that had enough been made, the organisms would have been found. This probably is true, but it is also true that examinations were made no less frequently than in the cases of proved typhoid.

TABLE 9.—NUMBER OF BACTERIOLOGIC EXAMINATIONS PER
CASE IN PROVED TYPHOID AND IN CLINICAL TYPHOID

Source	Proved Typhoid	Clinical Typhoid
Blood.....	1.33	1.40
Urine.....	0.87	1.08
Feces.....	2.08	3.20
Total.....	4.28	5.68

We have been unable to find convincing evidence that vaccination lessens the probability of finding the infecting organism, and submit this series merely as cases in which the invading organism is unusually hard to demonstrate. The figures given are, moreover, somewhat misleading, because not in every case were five examinations made. In some there were only one or two, while in others there were many more.

The average white counts for all days combined were 6,700 in clinical typhoid.

TYPHOID CARRIERS

In all, thirty-two carriers were reported, of which fifteen were of straight typhoid, five of paratyphoid B and six of paratyphoid A, while six more were indeterminate paratyphoid infections. Of these thirty-two patients, eighteen denied any previous history of typhoid and three admitted the disease, four years, thirteen years and fourteen years, respectively, before. The individual with a history of typhoid infection four years before also had had a typical paratyphoid B infection in November, 1916. He was found to be a carrier of the paratyphoid B organism. In the remaining eleven cases there was no note as to previous history of typhoid.

Ten of the thirty-two gave a definite history of diarrhea, either occasional or chronic, while seven gave a negative history for this condition. In the remainder it was not discussed.

In the group, twenty-eight had received saline triple vaccine and seven the lipovaccine. Four of these patients had received both. One case was not recorded as to vaccine. All seven patients vaccinated within one month before admission to the hospital had received the lipovaccine, and of these, four had been vaccinated several months previously with the saline preparation. Those thus vaccinated had been so inoculated from one to twenty months previously.

All but one of the thirty-two were of the intestinal type of carriers, while the last had a positive urine culture.

CAUSES OF TYPHOID FEVER IN THE VACCINATED

As was stated at the beginning, this study becomes a study of typhoid fever in the inoculated individual. The records of the 270 cases of straight typhoid studied showed that all had received prophylactic inoculations, and in 207 of them the dates and type of vaccine were recorded. The possible causes of failure of so-called vaccination to protect against typhoid may be thus enumerated:

1. *Absence of Vaccination, Either Total or Partial.*—By this I refer to failure not because of impotent vaccine but because of failure to react in certain individuals. It is well known that after the same doses of vaccine, different persons form differing amounts of agglutinins. But agglutinin titer is not a measure of immunity. We have no criterion that will tell us when an individual is actually immunized, nor have we any means of determining the degree of immunity present.

2. *New Strains of the Organisms Against Which the Vaccine Does Not Immunize.*—Serologic and cultural determinations made in the various laboratories have not consistently produced anything to suggest such a condition.

3. *Failure of Proper Inoculation.*—Among the cases of true typhoid studied, vaccination had been performed in fifty different camps and posts in the United States. This fact, combined with the really excellent results in most individuals vaccinated, renders such a possibility rather remote.

4. *An Overwhelming Dose of the Infecting Organism.*—Absolute immunity to human disease does not exist in man. The highest immunity that can be produced by artificial methods will protect against the antigenic virus only up to a certain limit. I am of the opinion that the greater number of cases of typhoid and

paratyphoid in France occurred as a result of massive infection with a dose great enough to overwhelm the forces of immunity. This, I presume, was most frequently associated also with the first cause enumerated, "absence of vaccination, either total or partial," in that it occurred in those possessing a lower degree of immunity than their more fortunate comrades. As Bernard has so succinctly expressed it, vaccination raises against the typhoid bacillus a great barrier—high, but not insurmountable.

5. *"Back-Handed Typhoid," "Antibody Exhaustion" or "Immunity Exhaustion."*—I include the second designation of this condition as being the most readily comprehensible in view of the existing nomenclature and conceptions of immunity, while I prefer the third as being more scientifically correct. I developed the first term as I recognized more and more of this type in the field, and it has the particular advantage that it emphasizes the assumption that the successive stages of typhoid infection are therein, in a manner, reversed.

The present day conception of typhoid is that of a primary systemic infection. The organisms entering by way of the gastro-intestinal tract are absorbed into the circulation and do not primarily grow as saprophytes in the alimentary canal. After passing through the gastro-intestinal mucosa, the organisms reach the liver through the portal circulation, where they may be excreted through the bile; or some may pass into the general circulation, where they multiply and, after the usual period of incubation, cause typhoid fever. The organisms excreted in the bile may lodge in the gallbladder and there, growing, produce the carrier condition, even though the host has not had typhoid fever.

In a vaccinated person, the organisms entering the portal circulation are either broken up and destroyed by the body ferments or excreted into the bile, or both. In the gallbladder they may find lodgment and continue to grow, in reality outside the body organism, multiplying profusely even though the host be highly immune. The numbers of organisms that are continually discharged in the bile and resorbed through the intestinal mucosa call on the immunity mechanism for constant and exhausting action. There may be superimposed on this a local enteritis caused by one of the typhoid-colon group or any other organism, or even by the typhoid member of the group itself. This subacute or chronic condition, rendering toxic absorption more facile, serves gradually to undermine the constitution. Finally, added to all this, are the hardships of war and army life—exposure, food not always well balanced, fatigue, and perhaps at last some intercurrent infection—and all the conditions required to wear out a body immunity are then present.

It is this reversed process—a local infection or carrier state followed by systemic disease instead of the usual typhoid followed by a carrier condition—that I have chosen to call "back-handed typhoid." Overwhelming doses of the infecting organism and this exhaustion reaction were in my opinion two of the chief causes of typhoid among our troops.

From the nature of the condition it has been impossible to obtain convincing experimental evidence of its presence in France; but a certain amount of indirect evidence appears to warrant our assuming its presence. Our first case occurred in a colleague who, preceding his illness, had been billeted with a French family and who had been drinking unchlorinated water while at his billet. For two weeks or more he had been complaining

of general malaise and a moderate diarrhea, but not sufficient to keep him from his work. At the end of two or three weeks the illness became acute, the usual symptoms of typhoid developed, he became progressively worse, and he died within one week from the onset of the exacerbation.

These cases present the usual clinical histories of ambulatory typhoid, with the definite addition of a local gastro-intestinal pathologic condition and symptoms preceding the disease proper. Otherwise there is nothing unusual about the symptomatology. Especially frequent was this syndrome among the men who had seen active service at the front. From nearly all, a history was obtained of having drunk whatever water they could get, even from the stagnant mud of the shell holes.

To check up on the impression I had gained, I questioned 104 patients as to previous history of chronic local gastro-intestinal disturbance. All were straight typhoid cases. Forty-four denied attacks of diarrhea antedating the diarrhea of the disease itself. Thirty-nine admitted a continuous preceding enteritis varying from one week to three months in duration, and of these, twenty-three had had it for over one month. Fifteen had had diarrhea for from one week to three months while at the front, which had subsided and from which they had been free for from two to three months. Seven additional patients admitted having had a transient diarrhea of from one to five weeks' duration in the two months preceding their disease.

Subacute diarrhea is not a necessary nor the usual antecedent of typhoid fever. The disease begins frequently even with constipation. I would compare the foregoing figures, in which more than 60 per cent. had been afflicted with enteritis, with the statements of the Typhoid Commission in the Spanish American War, that in that epidemic "more than 90 per cent. of the men who developed typhoid fever had no preceding intestinal disorder." I do not believe that the figure of 60 per cent. would hold for all men attacked by this malady in the American Expeditionary Forces, but do assert that it was the case in a representative number of those who had been at the front.

There is no proof that these men were harboring the typhoid bacillus in their intestinal tract previous to coming down with the disease. It is here that my hypothesis fails of absolute proof. Such proof would have necessitated a survey of the stools of all the members of a division, to be followed by weeks or months of watching to see whether the carriers discovered would develop the disease. Moreover, had this been done, the carriers would have been hospitalized and treated, thus defeating the object of the experiment. But corroborative evidence is not lacking. Several observers have reported the finding of typhoid bacilli in the stools of patients a few days or more previous to the onset of the disease, while Battlehner¹² has reported four cases in whose excreta the bacilli were discovered from twenty-one to 117 days before the onset of the disease. These had been considered as healthy carriers. I have a record of one patient who one and a half months previous to admission cared for a typhoid patient and shortly thereafter developed diarrhea, which persisted for six weeks until the typical acute onset of typhoid. In the discussion of typhoid carriers I have called attention to ten out of the thirty-two carriers, with history of diarrhea, none of

whom had had preceding typhoid, and one carrier with no history of typhoid and no diarrhea, who, nine months previously at Camp Dodge, had had negative stools for the typhoid group.

I have shown, then, that carriers have been produced in France; that diarrhea is often associated with the carrier condition; that among 104 men, diarrhea preceded the disease in 60 per cent.; that in one instance exposure to the disease was followed by enteritis which persisted for six weeks, until the onset of typhoid. Before absolute proof of back-handed typhoid is produced, I must show that all these facts find sequence in individual cases.

6. *Unsatisfactory Vaccine, Either as Regards Antigenic Properties or Number of Doses Administered.*—Considerable experimental evidence has accumulated to show that with increasing numbers of inoculations the immunity increases. Four inoculations confer a greater degree of immunity than do three. One of the advantages of the method in use in the United States Army is that the men nearly all received the same vaccine in the same dosage and with the same number of inoculations. Observers in other armies were sometimes forced to draw their conclusions from patients who had received different kinds of vaccine and all numbers of injections, from one to four or more. The fact that our vaccine did protect in the great majority of the cases demonstrates the efficiency of our preparation and of the dosage. It may not be ideal, but it is thoroughly practical.

Reed, Vaughan and Shakespeare, in their report on typhoid in the war with Spain, draw these conclusions:

Typhoid fever is so widely distributed in this country that one or more cases are likely to appear in any regiment within eight weeks after assembly. With typhoid fever as widely disseminated as it is in this country, the chances are that if a regiment of 1,300 men should be assembled in any section and kept in a camp *the sanitary conditions of which were perfect*, one or more cases of typhoid fever would develop.

More than 90 per cent. of the volunteer regiments developed typhoid fever within eight weeks after going into camp.

Even an ocean voyage does not relieve an infected command from its infection.

About *one fifth* of the soldiers in the national encampments in the United States in 1898 developed typhoid fever.

We are prone to think of typhoid fever as being no longer prevalent in the United States. We must remember that more than 150,000 typhoid cases still occur each year, and that, according to Gay, these cause an annual production of 7,500 carriers. We may assume that the statements made in 1898 are equally true in 1919.

Official reports with the accurate numbers of cases of typhoidal infection in the American Expeditionary Forces will not be available for several months; but this total will be below 2,000 cases. This, with a total of more than 2,000,000 men transported overseas, represents a typhoid incidence of less than 0.1 per cent. Although antityphoid vaccination is partly responsible for this diminution in typhoid incidence compared with Spanish-American War figures, a place of great importance must be given to improved sanitary procedures.

SUMMARY

An attempt has been made in this report to study from the point of view of the clinician the disease produced by *Bacillus typhosus* when it invades the body of a person previously vaccinated against that organ-

12. Battlehner, R.: Dissertation, Strasbourg, 1910.

ism. There has heretofore been some difference of opinion as to how much antecedent vaccination will change the clinical picture of the disease. Recent work by several observers tends to corroborate the conclusions reached in this study.

A series of 270 cases in which it was proved by successful cultivation experiments that the patients were infected with *B. typhosus* forms the basis of the work. Although I have accepted in my report all cases reported since January, 1919, it must be borne in mind that in a sense we are dealing with a selected series of cases. That is, I have accepted only those in which we succeeded in isolating the organism. It is possible that many more cases of disease caused by the same germ occurred, but from which the organism could not be isolated. In this connection I have discussed the condition known as clinical typhoid fever in which the symptomatology was characteristic, but in which bacteriologic studies were without result. In the latter type I concluded that the typhoid bacillus or one of the typhoid group of organisms was the etiologic factor, but that its presence was demonstrated with much greater difficulty. On the other hand, I would call attention to the fact that in the 270 cases there was no difficulty in obtaining the germ, its presence in blood, urine and feces being noted in about the percentage usually described for typhoid in non-vaccinated persons.

Throughout the discussion we must bear in mind that a great number of mild and abortive cases of true typhoid may have occurred—cases in which the patients were never sick enough to be sent to the hospital, but which would have been typical typhoid had the patients not been vaccinated against the disease. I agree that there may have been hundreds or even thousands of such cases, how many we shall never know. Surely, many vaccinated persons drank typhoid bacilli and destroyed or excreted them, remaining totally unaffected by the exposure. Surely, also, many did react slightly to the exposure, perhaps with no further symptoms than a rise of temperature of a degree or more during a few hours or a day. It is this reaction which proves that they are immune and are destroying the organism almost as soon as it invades the body—in fact, that they are *not* going to develop typhoid fever. Such a person, though temporarily infected with *B. typhosus*, certainly cannot be said to be suffering from typhoid fever. If the clinical conception of the disease were so amplified as to include all these cases, we should have to admit that practically every vaccinated person when he ingests the germ develops typhoid fever: a *reductio ad absurdum*. There are probably all gradations from these simplest febrile reactions up to the typical typhoid fever as described. It becomes, then, a question at what stage the manifestation is to be given the name typhoid fever.

When the average man in the army really feels ill, he goes to the hospital. Particularly was this true during the period of this report, when there were no activities at the front—nothing more entertaining than “daily fatigue.” So, using the point of view of the clinician, I will arbitrarily say that when a man is admitted to the hospital as a result of typhoid infection he has typhoid fever, and that the others are successfully combating the disease with their immunity mechanism. This is purely arbitrary, and I would emphasize the point that the division is placed here so that we may have a basis for clinical comparison of the disease with

the typhoid of the nonvaccinated as they have been studied in hospital. I do not lose sight of the fact that the epidemiologic phase of the situation is far different—that every one of the mildly infected must be considered as typhoid individuals capable of spreading the organism broadcast.

There is no way of telling how many patients with typhoid infection were admitted to the hospital and never recognized as such. The number may have been great or small. A direct attempt to reduce it to a minimum was made at the inception of our work by the issuance from the chief surgeon's office of a rather lengthy circular letter which was sent to all hospitals and medical organizations, directing attention to the disease, describing both the typical symptomatology and that supposed to be found in the vaccinated, and dwelling in particular on the necessary care in differentiating the disease from influenza. All medical officers were requested to watch particularly for the disease in its atypical forms, and to request a laboratory confirmation in any case of doubt. The success of this attempt was indicated by the large number of clinical typhoids and typhoid suspects reported to the division of laboratories and infectious diseases.

In the study of our 270 cases of proved typhoid I have dwelt at some length on the routine laboratory examinations because I consider it desirable to show that in this field as well as in the syndrome of typhoid in the vaccinated, there is no essential difference from the findings in the nonvaccinated. Ten per cent. of relapses might appear a trifle high, but series in the nonvaccinated are reported with this figure. The delay in noting the appearance of rose spots and palpable spleen until the twelfth day, on an average, was probably due to the fact that these signs were not recognized on the first day of their appearance. Those cases studied personally by myself and certain co-workers showed these important signs, as a rule, earlier.

The total mortality in those who did contract the disease has not been shown to be lessened. Ten or 11 per cent. has been the generally accepted mortality for typhoid, but most of these figures have not differentiated between typhoid fever and the paratyphoids. Such, for example, is true of the figures of Osler and of Reed, Vaughan and Shakespeare cited above. It is possible that the mortality for typhoid fever among the nonvaccinated, considered apart from the paratyphoid infections, is higher than 10 per cent. Under any circumstances our figure is more likely to be too high than too low. Severe cases were not in such danger of misdiagnosis as were the mild ones.

Our records do not give us conclusive information on one point that would be of considerable interest to the epidemiologist, that is, the relative efficacy of saline vaccine and lipovaccine. By far the greater number of patients had received the saline vaccine; but those receiving the lipovaccine had the higher mortality. Furthermore, the time interval since inoculation was as a rule much shorter in the case of the lipovaccine. No just comparison can therefore be made.

CONCLUSIONS

1. A study of 270 cases in which the patients, all of whom had received triple typhoid vaccine, were infected with *B. typhosus*, leads to the conclusion that in these hospital cases the clinical picture of typhoid in the vaccinated was similar to that of the unvaccinated. Absence of leukocytosis, continued fever of the usual course and duration, rose spots, palpable spleen,

relapses and complications all remained characteristic of the disease.

2. In our series the mortality was 11 per cent.

3. Positive cultural results from blood, urine and feces were of about the same percentage as with non-vaccinated patients, and the duration of the bacteremia appeared to be the same.

4. Patients infected within eight months after vaccination had an average severity (fatal percentage combined with "severe" percentage) of less than 10 per cent. After eight months, the severity percentage gradually increased. Our figures for later months are not complete enough to allow us to draw conclusions as to the period of maximum immunity.

5. The onset of the disease was more frequently acute when occurring within the first month after inoculation.

6. In sixteen cases with onset from seven to twelve days after inoculation (the usual incubation period), the infection probably occurred during the interval after inoculation.

7. The paratyphoid infections, although much milder as a group, could not be clinically distinguished in individual cases from straight typhoid. They were of much less frequent occurrence than was the latter.

8. It is probable that a large number of vaccinated persons were infected with *B. typhosus* and allied organisms who never became sick enough to require admission to the hospital. In these the immunity mechanism was eventually successful in combating the infection, so that they did not develop clinical typhoid fever. Their epidemiologic importance is recognized. This report deals with the remaining persons—those who in spite of vaccination developed the disease.

9. There are six possible causes of failure of vaccination to protect against typhoid; a new clinical variety is for convenience called "back-handed" typhoid.

10. The incidence of the typhoid group of diseases in the American Expeditionary Forces was less than 0.1 per cent., as compared with 20 per cent. for the Spanish-American War.¹³

INDUSTRIAL BLOOD POISONS

C. R. NEWTON, M.D.

AKRON, OHIO.

Some months after the outbreak of the war, large users of anilin, finding themselves deprived of their usual source of supply, were compelled to engage in the manufacturing business for themselves. Before manufacturing methods were improved, and the process finally discontinued, a number of benzene (benzol, C_6H_6) and anilin intoxications occurred which I had the opportunity to study first hand, and the most important of which are herewith reported.

REPORT OF CASES

CASE 1.—*Benzene intoxication*.—Mr. A., chemist, aged 30, in charge of operations, who had been working intensively in benzene for about two weeks, complained, June 12, 1916, of headache, anorexia, lassitude and loss of weight. Suddenly pain in the abdomen developed, accompanied by

nausea and vomiting. Physical examination detected nothing abnormal. Temperature and pulse were normal. An examination of the blood, however, revealed a marked leukopenia. The blood was normal in color, but seemed to be lacking in viscosity. There were 5,760,000 red blood cells per cubic millimeter; 1,200 white blood cells; hemoglobin, 85 per cent. (Sahli). The differential count revealed: large mononuclears, 39 per cent.; small mononuclears, 0; polymorphonuclears, 54 per cent.; eosinophils, 0; transitionals, 0.6; other cells, 0; total, 93.6 per cent.

The intoxication in this case was largely from inhalation. Aside from the blood findings, the physical picture is that of a nervous dyspepsia, which was probably true in this case, as the man was of a nervous temperament and anxious over the responsibility of his position.

After a month's leave of absence with complete rest, the leukocyte count became normal and the patient made a complete recovery. It was not our observation that a leukopenia alone, of the severity herein described, would cause symptoms. This view is supported by observation of the following cases:

CASE 2.—*Benzene intoxication*.—Mr. B., chemist, aged 26, exposed about two weeks, with no symptoms, when examined, June 15, 1916, gave a red blood cell count of 4,000,000; white blood cells, 1,250; hemoglobin, 95 per cent.

July 12, after the man had been instructed, but allowed to continue work, the red blood cell count was 4,352,000; white blood cells, 3,200; hemoglobin, 95 per cent.

CASE 3.—*Benzene intoxication*.—Mr. C., chemist, aged 35, exposed about two weeks, with no symptoms, when examined, June 15, 1916, gave a red blood cell count of 3,680,000; white blood cells, 1,700; hemoglobin, 90 per cent. The differential count was: large mononuclears, 9.6 per cent.; small mononuclears, 17.6; polymorphonuclears, 69.6 per cent.; eosinophils, 0; transitionals, 0.32; total, 97.12 per cent.

July 12, after being advised, but allowed to continue work, the patient's red blood cell count was 4,032,000; white blood cells, 3,800; hemoglobin, 90 per cent.

Both of these men completely recovered.

CASE 4.—*Benzene-anilin, mixed intoxication*.—M. S., aged 45, laboratory helper, inhaled vapors from an anilin reducer and received a mixture of anilin and free or unreduced benzene, which is occasionally present in an anilin reducer. The patient was seized with headache, chills, nausea and vomiting. I saw him, Oct. 20, 1916, within a few minutes after the onset of the symptoms. He was very cyanotic. The pulse was dicrotic, rate 110. The systolic blood pressure was 119; diastolic, 73. The blood was dark brown. The red blood cell count was 5,200,000; white blood cells, 10,200; hemoglobin, 90 per cent. (Sahli).

October 21, sixteen hours later, the cyanosis was gone, the pulse was of good quality, the systolic blood pressure, 137; diastolic, 92, and the blood normal in color. The red blood cell count was 5,600,000; white blood cells, 1,440 (check by another, 1,200); hemoglobin, 90 per cent.

October 24, seventy-two hours later, the patient felt well and was anxious to return to work. The red blood cell count was 5,491,000; white blood cells, 6,640; hemoglobin, 92 per cent.

The interesting observations in this case were the selective action of benzene on the white blood corpuscles, the depression of blood pressure, and the rapid recovery.

CASE 5.—*Anilin intoxication*.—R., aged 49, employed twelve years, climbed inside an anilin reducer, June 26, 1916, to clean out sludge with hose. He had worked only a short time when he began to feel dizzy and nauseated, and to experience a "warm sweet taste" in his mouth. With presence of mind he quickly climbed out of the reducer and was assisted to the hospital. According to his account, he did not entirely lose consciousness, but seemed to be overcome by mental confusion and great bodily weakness. I saw him within an hour after the onset of the symptoms. The picture was that of collapse. The complaint was headache and chilliness, although the man was perspiring freely. The skin and mucous membranes were intensely cyanotic; the temperature was 101 F.; the pulse was weak and dicrotic, rate 110. The

13. In addition to the references already given, the following will be found of interest:

Vaughan, V. C., Jr.: Report on Typhoid Fever in Troops Stationed in the Vicinity of Marseilles.
Freeman, A. W.: Med. Officer, London, 17: 71, 1917.
Vaughan, V. C., and Palmer, G. T.: J. Lab. & Clin. Med. 3: 635 (Aug.) 1918; *ibid.* 4: 587 (July) 1919.

systolic blood pressure was 110; diastolic, 60. Six hours after the administration of 3 grains of camphor hypodermically, the blood pressure rose to 130 systolic and 85 diastolic. The blood was chocolate brown, flowing very freely. The red blood cell count was 3,520,000; white blood cells, 10,600; hemoglobin, 95 per cent. The differential count revealed nothing important. Owing to a peculiar strangury, the patient was unable to void for several hours. The urine, when obtained, was dark, and contained no sediment. Its specific gravity was 1.020; it was acid in reaction and negative for albumin, sugar and bile. There was a trace of anilin. Methemoglobin could not be demonstrated in the urine.

June 30, the man still had headache and complained of soreness in his chest. He was still cyanotic, though improved. The pulse was very soft, the systolic blood pressure, 115; diastolic, 60. The red blood cell count was 2,944,000; white blood cells, 4,400; hemoglobin, 95 per cent. The urine was normal in color with negative findings.

July 7, he was still slightly cyanotic, but headache had disappeared. The pulse was 88, and of much better quality. The red blood cell count was 3,112,000; white blood cells, 4,140; hemoglobin, 90 per cent.

July 13, he was no longer cyanotic. He felt well except for slight nervousness and insomnia. The red blood cell count was 4,208,000; white blood cells, 4,300; hemoglobin, 91 per cent.

CASE 6.—*Anilin intoxication*.—S. B., aged 41, washed some clothing in anilin, Oct. 30, 1916, and immediately became ill, complaining of weakness and headache. Cyanosis was pronounced. His temperature was 99.5 F. The pulse rate was 88, the systolic blood pressure was 130, and diastolic, 98. The blood was chocolate brown. The red blood cell count was 3,420,000; white blood cells, 8,040; hemoglobin, 88 per cent. The urine was dark colored, with negative findings.

November 6, he was much improved. The blood cell count was 5,024,000; white blood cells, 8,800; hemoglobin, 90 per cent. The temperature and pulse were normal.

CASE 7.—*Anilin intoxication*.—J. K., aged 40, poured iron into an anilin reducer and inhaled the fumes, July 12, 1916. He became ill with headache, dizziness, cyanosis and perspiration. The temperature was 99 F., pulse 96, water hammer type. The systolic blood pressure was 112, diastolic 60. The red blood cell count was 2,262,000; white blood cells, 4,800; hemoglobin, 92 per cent. The differential count was not important. The urine was dark colored with negative findings. The patient made a complete recovery.

CASE 8.—*Anilin intoxication*.—N. M., aged 28, poured iron into an anilin reducer and inhaled the fumes, Aug. 9, 1916. He became cyanotic and complained of headache. The temperature was 98 F. The pulse was 92 and of good quality. The systolic blood pressure was 118 and diastolic 75. The blood was chocolate brown. The red blood cell count was 4,160,000; white blood cells, 4,400; hemoglobin, 95 per cent. The patient was unable to void for several hours.

August 10 he was much improved, but was still cyanotic. The red blood cell count was 3,800,000; white blood cells, 6,200; hemoglobin, 95 per cent. The urine was dark amber with negative findings.

August 16 the red blood cell count was 4,000,000; white blood cells, 6,000; hemoglobin, 95 per cent.

In this case, although the cyanosis was pronounced, and the blood very dark, the cell destruction was slight. The poison apparently overwhelms the oxygen carrying capacity of the blood by the formation of methemoglobin, which may be more important in producing cyanosis than either disintegration of the red cells or formation of anilin black, as described by Engelhardt.¹

CUMULATIVE ACTION

In December, 1916, I began the study of ten cases subject to more or less exposure, to determine if possible the cumulative properties of benzene. The service of these men ranged from one week to five years and

seven months. Monthly blood counts were made, and all were found to be practically normal.

It is my opinion, not that benzene and its amino-derivatives possess any very definite cumulative action, but that the anemias of which they are the cause follow a definite intoxication or a series of definite intoxications. It remains to be determined, however, whether or not the constant inhalation of even minute quantities of benzene vapor from spreading machines, cement cans and other sources would tend to interfere with proper oxygenation of the blood and tissues, even when there is no cell destruction, and thus undermine the worker's resistance to disease.

CONCLUSIONS

1. Workers chronically exposed to benzene may show leukopenia without any other symptoms, and make complete recovery.

2. Acute exposure to anilin and nitrobenzene vapors produced cyanosis with destruction of the red blood corpuscles, but with little change in the white corpuscles, with recovery. In one case in which free benzene was presumably present, there was destruction of white cells without appreciable destruction of red cells, and a more rapid recovery, that is, in three days.

3. The maximum white cell destruction by benzene, and the maximum red cell destruction by anilin-nitrobenzene, may not be reached for several hours after the onset of the symptoms.

4. Workers exposed for long periods to benzene may not have a leukopenia; apparently, therefore, the action is not cumulative.

PARAPLEGIA AFTER ARSPHENAMIN IN A CASE OF RETROBULBAR OPTIC NEURITIS*

T. J. DIMITRY, M.D.

NEW ORLEANS

This case is presented not solely for its extremely interesting features, but to some extent because of the arbitrary attitude of some of my confrères in attributing a sequence of the usual syndrome to be expected in an acute optic neuromyelitis of syphilitic causation to the administration of arsphenamin. Furthermore, the number of cases of the incongruous syndrome of retrobulbar optic neuritis with myelitis reported in the literature is limited, and the beneficial effects of arsphenamin on the retrobulbar neuritis, while the same remedy seemed to be the exciting agent in the development of the paraplegia, add increased interest.

History.—A man, aged about 34, unmarried, complained that his sight was failing him, one eye being, in fact, practically blind. This eye condition started, May 1, 1918, with a constant pain in the eyes, and a deeper pain both on movement of the eyeballs, and when the eyes were pressed back into the socket. He had always considered himself healthy, though he was of delicate structure. The family history was negative and did not show anything of interest, neurologically or otherwise. The patient had had the usual diseases of childhood, which apparently had no bad effect on him. He emphatically denied any venereal disease. He consulted his first oculist, May 3, when the vision of the right eye was 20/50 and of the left eye 20/15. Ophthalmoscopically, the fundus was reported negative. The vision in the right eye was not improved by lenses. Dark glasses and zinc drops

* Owing to lack of space, this article is abbreviated by the omission of a bibliography. The complete article appears in the author's reprints.

were prescribed. Pain continued in the eyes, and, May 7, vision had fallen to 20/200 in the right eye and 20/20 in the left. His refraction, on being determined again, showed no improvement, and the fundus was reported normal. A solution of atropin was instilled, and this greatly lessened the pain in the eyes.

May 8 he consulted a second oculist, who also found the fundus normal and could not account for the loss of vision.

Examination.—May 10, the patient consulted me. The vision was 15/200 in the right eye and 20/40 in the left. Ophthalmoscopically, the fundus details were negative. There was no diplopia, though there was a slight nystagmus in the right eye. The sinuses, as a possible cause of the blindness and the pain in the eyes, were ruled out. The field of vision showed the colors reversed, the spiral fatigue field of neurasthenia, and a central color scotoma present. The neurologist reported the patellar reflex exaggerated in one leg and sluggish in the other. This neurologic examination was so void of any aid in the diagnosis that a buried complex was thought of, and a tentative diagnosis of hysteria was made. The patient was advised to continue going to his office and to consult me the next day. He followed these instructions, and while on his way to the office he fell into a street excavation, slightly injuring his knee. It is questionable to what extent his impaired vision was a factor in this fall, for it was learned that for some time indefinite pains had caused him to use a pillow behind his back while driving his car, that he had been suffering from paresthesias in his legs, which had been quite annoying, and that some slight urinary disturbance had been present.

Despite the fact that the patient had recently gone blind in one eye, and the other was rapidly failing, he seemed unconcerned. This mental state changed in a few days, and he became so irritable that he was taken to an institution, May 13.

The neurologist who accompanied him remarked for the first time that he did not walk well, and that he appeared weak in the legs. His mental state was now such that it became necessary to resort to sedatives and hypnotics.

The Wassermann reaction by the original method and that of Tschernogowbou was negative. The total leukocytic count was 5,500. The differential count was: neutrophils, 66 per cent.; lymphocytes, 28 per cent.; large mononuclears, 6 per cent.

The specific gravity of the urine was 1.021. Its reaction was acid.

Tests for albumin, sugar, acetone and diacetic acid were negative; for indican, positive. Microscopic examination revealed an excess of leukocytes, much mucus, and hyaline and granular casts.

The patient suffered a complete loss of sight before any other symptoms developed to make possible a diagnosis, though some precursory symptoms obtained in his history were not recognized at the time as being important. A conspicuously healthy eye interior, ophthalmoscopically, in a blind patient offered no explanation, and it seemed that the nearly scientific branch of medicine, ophthalmology, must resort to that meaningless term "amaurosis."

Daily fundus examination elicited no information until the morning of May 13, when there was discovered a distinct elevation of the optic nerve of both eyes. This elevation was greater in the right eye. The pupils were widely dilated and did not respond to light. The patient's mental irritability and the choked disk made me suspicious of a brain tumor; hence, no spinal puncture was made at this time. Tuberculosis was ruled out by physical examination and roentgen-ray studies. A roentgenogram of the cranium was negative.

Treatment and Result.—On the afternoon of May 14, 0.06 gm. of arsphenamin was administered intravenously. On the following morning, the patient complained of stiffness in the legs, and pain in the back, and he asked that a hot water bag be placed over the region of the kidneys, for he had not voided his urine. It was then found that he could not move his right leg, and during the afternoon this paralysis extended to the other leg. It was necessary to catheterize the bladder and later to contend with an overflow of the urine. He suffered an inability to evacuate the bowels, and subsequently an incontinence of feces. He developed decubitus and a very

painful hyperesthetic area of the left arm. The paralysis of the legs was absolute, and all voluntary motion, and sensation in all its qualities, including temperature and touch, was destroyed. Different degrees of deep and superficial anesthesia and hyperesthesia extended to within an inch of the nipple anteriorly, and not quite so high posteriorly. The reflexes were abolished in the legs with a flaccid paralysis, and the appearance of a rapid wasting. The whole presented a picture very alarming.

Two days after the injection of arsphenamin, the elevation in the optic nerve had improved and within the next day had disappeared entirely, leaving a normal appearing optic nerve, though the patient was blind.

As there was no longer fear of intracranial growth, a spinal puncture was made. It must be remembered that this puncture was made after the paraplegia developed; needle traumatism or introduced infection could not have been the cause for the paraplegia. When the definite paraplegia did develop, the diagnosis "retrobulbar optic neuritis with myelitis," both of syphilitic causation, won my acceptance only after a careful study of the literature of these associated conditions; and this diagnosis is confirmed by the laboratory tests and the therapeutic results obtained.

Spinal puncture was made, and during the operation the back was found rigid and offered some difficulty to the introduction of the needle. The fluid was clear and was not under pressure but, to the contrary, was obtained drop by drop. The pathologist who examined the fluid reported that with 0.75 c.c. of fluid, the Wassermann test was negative; the cell count was 173; the globulin test was ++++; smears for tubercle bacilli were negative; the colloidal gold test yielded a clear-cut zone reaction, indicative of, or in accord with, that found in tuberculosis; cell differentiation revealed: polymorphous neutrophils, 1 per cent.; lymphocytes, 95 per cent.; endothelial leukocytes, 3 per cent.

A provocative blood test was found negative.

In spite of the apparently harmful effect of the arsphenamin, a second dose of 0.06 gm. of arsphenamin was given, May 21, and a dose of 0.09 gm. of neo-arsphenamin was given a few days afterward. Mercury was used by inunctions and the iodids were used in increasing doses, and for weeks the patient was taking 75 drops of saturated solution of potassium iodid three times a day.

I relinquished the case, June 19, and from that time on the only other medication was strychnin and electrical stimulation. Jan. 14, 1919, the patient informed me by mail that he could then walk and had a vision practically perfect. Jan. 24, 1920, he was on the streets getting about without any assistance, but there remained some bladder disturbance.

COMMENT

Did the arsphenamin produce the acute transverse myelitis? We know that the retrobulbar optic neuritis existed before the drug was administered, and its use produced an improvement in the optic nerve elevation. I did not think that the drug produced the myelitis, and I emphasized this belief by repeating the drug and a third injection to the benefit of the patient. There was no increased harm produced by the repeated injections; to the contrary, the patient improved. He again saw and walked. Apropos of the foregoing is a case report by Elschnig¹ on "a case of retrobulbar optic neuritis with myelitis," in which he says: "The eyes were affected first, and during the treatment paralysis developed and the patient refused further treatment." Ullrich von Hutten² thought, as did others, that "paralysis in syphilis was to be attributed to the use of mercury." In the same book³ in which he makes this observation there is a report of a case of "acute myelitis with decubitis developing during the use of mercury inunctions." Will history

repeat itself and arsphenamin run the same gamut? I fear it will.

McCaskey⁴ reports four cases from the literature and one that he observed in which paralysis developed after the use of arsphenamin. All of these patients were syphilitic. All received more than one injection. One received a Swift-Ellis treatment and another a subdural injection. It is extremely doubtful in my mind that these cases are to be explained on purely toxicological grounds, though the bad effect was produced by more than one injection. Other drugs have been thought to produce paralysis. Webber⁵ states that "the use of strychnin given before a relapse in myelitis is a circumstance demanding special notice," for he has seen bad effects following the use of strychnin in disease of the spinal cord, and he does not feel justified in using it.

Collins⁶ reports a case of sudden paraplegia occurring after the injection of "autolysin" in a syphilitic subject. He says: "The autolysin was a coincident in the production of the paraplegia and he could not eliminate syphilis despite the negative state of the blood and the spinal fluid."

Socin⁷ reports a case in which "a woman, aged 38, with a history of abortions and miscarriages, whose husband died of softening of the brain, suffered with a syphilitic eruption on the body. She received two doses of arsphenamin. The second dose produced an encephalitis and a severe affection of the spinal cord, with a decubitus. The patient died. The study of the cord was interpreted as a toxic myelitis." I hesitate to accept his interpretations, for we lack exactness and undoubted proof in differentiating a toxic spinal lesion that might be confused with syphilitic condition. It is for us to discover more readily the spirochete and clarify this doubtful etiology.

Then is not arsphenamin injurious to nervous tissue?

Erlach states that the drug is not injurious to nervous tissue. The drug was thought at one time to have an unfavorable influence on the optic nerve but not the cord. This was probably the outcome of the injurious effect of atoxyl and other aromatic arsenic preparations.

Schoenburg⁸ says that to those who have used a great deal of arsphenamin in syphilis of the central nervous system, "one thing is clear, namely, that it is not injurious to the healthy or damaged optic nerves if administered in proper doses and at proper intervals."

St. John Johnson⁹ experimented on rabbits with arsphenamin as to its therapeutic and toxic doses. Twelve rabbits were thoroughly impregnated with arsenic by arsphenamin injections. The dose of 1 decigram was lethal to but three rabbits; the others lived throughout the treatment, and at necropsy, arsenic was recovered in the tissues examined. In none of the twelve was an optic neuritis to be produced. These experiments, taken in connection with the fourteen cases of optic neuritis discovered during the survey of patients before or during the treatment of syphilis in which the optic nerve lesion disappeared rapidly under arsphenamin treatment, show that in these cases at least, arsenic had no influence on the development of an inflammation of the optic nerve; rather contrariwise; when neuritis had already developed, the specific treatment caused

rapid resolution. Thus it seems, Johnson concludes, the fear of production of blindness by therapeutic doses of arsphenamin is unwarranted.

The evidence presented justifies a parallel deduction as to its harmful effect on the spinal cord.

Further possibilities arose in the production of the paraplegia, demanding an explanation. In the case that I report was it a Herxheimer reaction? This reaction is an inflammatory response noted after the use of specific treatment in syphilis and is alone observed in syphilitic subjects. The reaction is spoken of as a disturbance of the endotoxins, and an excitation of the spirochete by insufficient dose of the drug.

I hesitate to accept as an explanation of this reaction that it is dependent on a questionable endotoxin or even on a toxin. The reaction might be explained as an indirect focal protein reaction, and this is occasioned by dead spirochetes. I believe, not that this was a Herxheimer reaction, but that it was a case of retrobulbar optic neuritis with myelitis, which is a definite clinical entity, and the paraplegia must play its part in the syndrome.

Hillion¹⁰ defines the process as a clinical syndrome characterized by a diffuse myelitis, oftenest acute, preceded, accompanied or followed by an optic neuritis.

This clinical entity, so well defined, dates to the writings of Erb and Steffan, who in 1879 reported a case of transverse myelitis in association with a retrobulbar neuritis.

Goulden¹¹ collected fifty-two instances. The eye symptoms appeared first thirty-six times, the spinal cord symptoms ten, and there was simultaneous appearance of eye and cord symptoms three times. The order of appearance was not stated three times.

The cases reported by Dreschfeld, Knapp, Chisholm, Mohokian and Hennenberg showed a definite choked disk. A great number of all the cases were without fundus changes at the beginning, though the eyes were blind.

Weisenburg¹² states that there is rarely a return of vision, and that there are only three cases on record in which the return of vision was complete. There was usually a resulting white atrophy of the optic nerves.

The death toll has been at least 60 per cent., and thirty cases have gone to necropsy. In the anatomic and pathologic studies made, all are agreed that the optic nerve lesion presents the same pathologic condition as found in the cord, that is, a softening, a degeneration and a neuroglial proliferation.

Bielschowsky considers the neuritis primary and parenchymatous. Anatomic continuity of the lesion in the cord has not been demonstrated. Elschmig believes that the optic neuritis is interstitial and that the vision is destroyed mechanically.

The etiologic factor in the production is well stated by Nettleship,¹³ who says that in his experience fifty per cent. of the symptomatic retrobulbar optic neuritis cases in contradistinction to idiopathic are due to syphilis, and, further, that since 1899 experience has shown that a large percentage are caused by syphilis and in the future many so-called idiopathic cases will, with the aid of serum diagnosis and improved methods, come under this heading.

In my case, though the Wassermann test was negative both for the blood and for the spinal fluid, the other tests show that the etiology was that of syphilis. I have been able to compile seventy-two cases. Forty-six cases were studied most carefully. Of the forty-six, seventeen patients undoubtedly had syphilis, shown either by a lesion or an acknowledgment of having had the disease. Twenty-eight died. Necropsy was held on twenty-one. Either a total or a partial atrophy was the result in all cases but three.

The subject has been the occasion for theses by Hillion, Gault, Picqué and Faure. Hillion reported forty-five cases. Devic reported twelve cases; Taylor gives a bibliography of twenty-five references.

CONCLUSION

It is well to remember that syphilis presents a vagary of symptoms at times lacking a definite explanation. What appears as an incongruous syndrome both pathologically and clinically is very often to be made clear when syphilis is taken into consideration, and an appreciation of the changes that might occur from a syphilitic arteritis, better known as a Huebner arteritis. To rid ourselves of dissenting opinions in unclassical cases, it will be essential to find the spirochete present. Then we may emphatically state the existence of the syphilitic disease.

EPIDEMIC ACUTE HEMORRHAGIC JAUNDICE OF TOXIC ORIGIN

ITS SYMPTOMS AND PATHOLOGY

DOUGLAS SYMMERS, M.D.

Director of Laboratories, Bellevue and Allied Hospitals
NEW YORK

During a period of ten weeks, commencing the middle of December, 1919, sixteen patients were admitted to Bellevue Hospital suffering from a variety of acute hemorrhagic jaundice. Of this number nine died—a mortality of 56.2 per cent. Clinically and anatomically the disease presents features which, on the one hand, are strikingly similar to those of infective jaundice and yellow fever, and, on the other, to acute yellow atrophy of the liver. Moreover, it has been a subject of remark that cases corresponding in all essentials to acute catarrhal jaundice have recently been received in numbers noticeably in excess of the routine experience of former years. It is possible that some of these represent a mild form of the epidemic disease, although in such patients stupor or delirium and hemorrhages are conspicuous by their absence, and recovery is the rule.

In eight of the sixteen cases of acute hemorrhagic jaundice, unsuccessful attempts were made to find spirochetes in stained films of blood taken from living patients. In addition, fresh blood or urine, depending on the stage of the disease, or both, were injected into guinea-pigs in an effort to reproduce the changes, as has been claimed in infective jaundice and yellow fever; as a routine measure 15 c.c. of blood were divided into equal parts and injected into the peritoneal cavity of three guinea-pigs, and 50 c.c. of urine, removed by catheter, were centrifuged, and from 2 to 5 c.c. of sediment, according to the total quantity procured, were injected into one or several guinea-pigs.

The results were uniformly negative. None of the animals dying spontaneously within the period of incubation—from six to thirteen days—or killed thereafter, showed the slightest indication of jaundice or hemorrhage. In three of the hospital patients, sections of the liver and kidney removed at necropsy were stained by the older method of Levaditi, but no spirochetes were found. In thirteen of the sixteen cases, blood cultures were negative; the others were not taken. In three patients who succumbed with symptoms of acute yellow atrophy of the liver, chemical examination for the heavy metals, particularly phosphorus, was negative (Dr. Gettler).

Of the sixteen cases, six were investigated by necropsy. In addition to jaundice and hemorrhages in the skin, mucous and serous membranes, various viscera and elsewhere, the kidneys were found to show cloudy swelling or necrosis of the tubular epithelium, while the changes in the liver varied from intense granular degeneration to those commonly described as acute yellow atrophy. In three instances the mucosa of the gastro-intestinal tract was greatly swollen and dirty grayish blue, while in the other three no changes were apparent to the naked eye, but were disclosed on microscopic examination.

In view of the fact that the disease occurs in epidemic form and is consequently to be expected in other quarters, its clinical aspects and the findings in those cases that were investigated postmortem are presented in this paper at some length.

SYMPTOMS AND PATHOLOGY

The prevailing type of epidemic jaundice, as we have seen it at Bellevue Hospital, is divisible into two symptomatic groups. The first group is characterized by jaundice of the conjunctivae, preceded, as a rule, by lassitude, digestive disturbances and other prodromes, and is accompanied by physical signs indicative of bronchitis. The patient takes to his bed, and in the course of the next few days jaundice becomes generalized and intense, the color is oftenest a greenish yellow, occasionally bright saffron, the conjunctivae are suffused, and hemorrhages are constant—epistaxis, hematemesis, melena, hemorrhagic vesicles about the lips and chin, and petechial or splotchlike extravasations in the skin or visible mucous membranes, in the former situation corresponding, in many instances, to scratch marks, the pressure of bedclothing, and other trivial injuries. By this time the mental condition of the patient is such as to fix the attention of the observer. The patient is languid, drowsy, stuporous or irritable and restless, sometimes irrational. The stools are clay colored. Vomiting and diarrhea occur but are not common. Frequently, indeed in the majority of cases, the patients complain of pain in various localities, and even though stupor be pronounced, signs of tenderness may easily be elicited by pressure on different parts of the body. In two of the Bellevue Hospital cases the combination of jaundice, clay colored stools, vomiting and epigastric pain and tenderness seemed to point to mechanical obstruction to the outflow of bile, and the abdomen was opened, but no cause was found. In the group under consideration, temperature, pulse and respiration are variable quantities, and appear to be determined largely by intercurrent conditions, such as bronchitis, pleuritis and the like. Moderate leukocytosis is the rule—from 11,000 to 24,000. The differential count is normal.

The urine contains albumin, bile and granular casts in abundance. At necropsy, these individuals show, in addition to the superficial signs of jaundice and hemorrhage, icterus of the deeper structures, notably the liver and kidneys, and hemorrhages in various tissues—the lungs, serous and mucous membranes, and soft tissues. In the lungs the physical signs seem to be due, in part at least, to the escape of blood into scattered groups of air vesicles. The kidneys show a degree of acute parenchymatous degeneration rarely surpassed, graduating not infrequently into necrosis of the tubular epithelium, diffusely or in large patches, with or without intratubular or interstitial hemorrhages. The liver exhibits cloudy swelling attended on occasions by dissociation of parenchyma cells and by fatty transformation and even death of cell groups, more particularly in those localities where bile imbibition is pronounced (the so-called icteric necrosis).

The second group is characterized by severe jaundice, wild delirium and rapid death. In such cases the liver presents histologic signs of diffuse necrosis, although the naked eye appearances may be those of a relatively well preserved organ. In other instances, necrosis of liver tissue is attended by innumerable hemorrhages, and the naked eye changes are then indistinguishable from those of the so-called acute yellow atrophy.

PATHOGENESIS

Perhaps the most illuminating feature in the pathology of the disease as a whole is to be found in necrosis of the gastro-intestinal mucous membrane without obvious interference with the escape of bile through the duodenal papilla. That bile does not escape, however, is shown not only by the degree of jaundice, but also by the acholic state of the intestinal contents, depending, apparently, on conditions in the liver cells and bile capillaries, rather than on mechanical obstruction to the exit of bile from the larger ducts. The changes in the gastro-intestinal mucosa are such as to suggest that the provocative agent is absorbed by the tributaries of the portal vein and conveyed to the liver, where the necrotic lesions correspond definitely to the distribution of the portal blood; that is to say, the liver lobules are destroyed, while the interlobular connective tissues with their blood vessels and bile ducts are relatively unchanged. The hemorrhagic extravasations in different tissues are secondary, most likely, to injury of the capillary endothelium by bile salts, promoted, perhaps, by lack of fibrinogen such as has been demonstrated in other destructive lesions of the liver, notably in experimental chloroform necrosis.

In view of the fact that we have not been able to produce the icteric and hemorrhagic changes in animals by the same methods that are said to yield positive results in so-called spirochetal jaundice, I am inclined to regard the disease under consideration as a toxic process, the reaction to which varies with the individual, some persons responding rapidly and with great violence, others more slowly and less severely. That the provocative agent is not being constantly renewed does not vitiate the contention, since it is known that the effects of certain poisons are delayed and that, once the liver is damaged in such manner that autolytic enzymes are released, a series of changes is initiated that becomes independent of the original cause. At the same time the toxic effects of bile are to be taken into consideration.

THE MORE PROLONGED CASES

CASE 1.—History.—A man, aged 55, who was admitted to Bellevue Hospital, Dec. 15, 1919, and who died, December 23, stated that for two months he had been troubled with "indigestion" and pain in the abdomen, most marked in the epigastrium. About ten days before admission the pain in the region of the stomach became intense, radiating to the back and shoulders, particularly the right shoulder. At the same time the patient developed symptoms of retching and was unable to retain food, vomiting immediately after eating, and there was severe diarrhea. On admission he was intensely jaundiced and very drowsy. During his stay in the hospital he was frequently irrational, and complained of itching of the skin. Muscular twitchings occurred at intervals and lasted for considerable periods. On admission the patient's temperature was normal and remained so for six days; on the seventh day it was 100.5 F., reaching 101 on the eighth day, where it remained until death occurred on the ninth. The white blood cells numbered 15,200; the differential count was normal; hemoglobin, 65 per cent. The urine contained albumin, and bile and granular casts were abundant.

Because of the jaundice, clay colored stools, vomiting and the intense pain in the abdomen, the patient was operated on and the gallbladder opened and drained. It was found to contain a moderate quantity of slightly viscid bile.

Necropsy.—There was intense jaundice of the skin and visible mucous membranes, the viscera, heart valves, etc. The lungs presented innumerable pleural and parenchymatous petechial or splotchlike hemorrhages. The kidneys were markedly enlarged and very flabby, diffusely greenish yellow, and friable. The substance was swollen and opaque, and the markings were irregular in distribution, the tufts, however, standing out as minute reddish specks. The mucosa of the stomach from one end to the other presented a dirty grayish blue, succulent appearance, and was swollen and irregularly covered by tenacious mucus, the rugae being flattened. The mucosa of the entire intestinal tract was similarly swollen, thickly covered by a milklike fluid, and the folds, particularly in the jejunum, were extraordinarily prominent, edematous and dirty pinkish. The liver was about normal in size, smooth, deeply jaundiced, the markings fairly distinct, and the cut surface somewhat resembling a nutmeg. No focal lesions were visible. The mucosa of the larger bile ducts was bathed in thin mucoid secretion, the duodenal papilla was patent, and no obstruction was apparent in the vicinity.

Microscopic Examination.—The liver cells showed marked dissociation, as if the liver had been given a severe shaking, the cells were cloudy, irregular in size and distribution, indistinct in outline, and their nuclei obscured. In many instances the central veins were distended by blood, and groups of intensely jaundiced liver cells were arranged circumferentially to the central vein or in streaks through the lobule. The kidney showed widespread granular degeneration, particularly the epithelium of the convoluted tubules, with desquamation of bile stained cells into the lumen. The mucosa of the stomach, duodenum and jejunum showed a superficial necrotic layer made up of pinkish-staining debris and glandular remnants, among which at intervals were numbers of red cells and nuclear fragments. The deeper capillaries were irregularly but intensely injected. The epithelial cells in the lowermost glandular tubules were apparently well preserved or slightly swollen and granular. The lung showed innumerable intra-alveolar hemorrhages in scattered groups.

CASE 2.—History.—A man, aged 54, who was admitted to Bellevue Hospital, Jan. 26, and died Feb. 3, 1920, stated that eight days before admission he had a chill followed by a splitting headache, but that previous to that time he had been feeling quite well. Three days later he was told that he "looked yellow"; and five days after this, when he was admitted to Bellevue Hospital, the conjunctivae and the skin of the entire body were deeply jaundiced. Just before admission the patient suffered a severe attack of epistaxis, and bleeding was still in progress on his arrival at the

hospital. The patient was languid, and there were small submucous hemorrhages in the lips and soft palate, and many punctate or slightly larger hemorrhages in the skin of the face. The epigastric and right upper regions of the abdomen were tender and resistant to palpation. For four days after admission the patient's temperature was normal. On the evening of the fifth day it was 103 F., and registered between 101 and 103 F. every evening thereafter until death. There was a well marked friction rub over the right side of the chest between the sixth and ninth ribs that became audible on the seventh day. The white cells numbered 24,000. The urine contained albumin, granular casts and bile. The day after admission the patient passed a tarry stool which responded to the guaiac test for blood. The Wassermann reaction was negative.

Necropsy.—The body was markedly jaundiced. There were several hemorrhagic specks in the region of the lips, and numbers of subendocardial hemorrhages. The mucosa of the stomach, duodenum and the first half of the jejunum was swollen, greyish green and gelatinous, bathed by a thin milk-like fluid. Pressure on the gallbladder was followed by the escape of bile through the duodenal papilla. The liver was about normal in size, bile stained, but otherwise showing no naked eye changes. The gallbladder was slightly distended by viscid bile. The right lung was the seat of a confluent lobular pneumonia, and abundant semipurulent fluid exudate was present in the corresponding pleural cavity.

Microscopic Examination.—Histologically, the most severe changes were apparent in the gastro-intestinal mucosa and in the kidneys. In the stomach and duodenum the mucosa was extensively necrotic. In places destruction of tissue was superficial, but at times practically the whole of the glandular layer was converted into pinkish-staining, structureless debris, in the tissues beneath which the capillaries were irregularly injected and distended. In the kidney the cells of the tubules, particularly in the cortex, were almost completely necrotic and were extensively desquamated and bile stained. Small hemorrhages were visible at intervals. The liver presented marked signs of cloudy swelling with dissociation of cells, and jaundiced areas were numerous, especially around the central veins, where many of the cells were undergoing necrosis.

CASE 3.—History.—A man, aged 60, who was admitted to Bellevue Hospital, Dec. 18, 1919, and died, Jan. 1, 1920, stated that for three weeks previous to admission he had been "feeling mean" because of general lassitude and aches and pains. His mental condition was such, however, that it was impossible to obtain an intelligent history. At the time of admission he was very irritable, but icterus was not apparent. On the second day after admission a yellowish tinge was noted in the sclerae, the next morning jaundice was distinct and the following day it was marked; hemorrhagic herpes appeared about the mouth, and epistaxis occurred. The patient was now extremely prostrated, irrational or stuporous by turns, and numbers of minute hemorrhages appeared in the skin. The edge of the liver was felt and the organ was tender, so much so that abscess was suspected. In the next two or three days, innumerable hemorrhages occurred in the skin, particularly in the line of scratch marks, and jaundice became extreme. The stools were clay colored. On admission the patient's temperature was 102; it rose to 104 F. on the second day, and by the fifth it fell to normal, after which it was subnormal until death, which occurred eleven days after admission. The leukocytes numbered 11,000. The urine contained albumin, casts and bile. The Wassermann reaction was negative.

Necropsy.—In addition to jaundice and superficial hemorrhages, necropsy revealed multiple hemorrhagic foci in the lungs. The liver was normal in size and consistency, and its icteric lobules stood out distinctly. Bile was expressed through the duodenal papilla, and no obstruction was apparent in or around the larger ducts. The gallbladder was slightly distended by thick, dark green bile. The mucous membrane throughout both the stomach and intestine was swollen and greenish gray. The kidneys showed no noteworthy naked eye changes.

Microscopic Examination.—The liver cells were swollen and cloudy and, in the immediate vicinity of the central veins, crowded with bile. There was marked granular degeneration of the tubular epithelium of the kidney and injection of its smaller blood vessels. The gastro-intestinal mucous membrane showed advanced and widespread alterations. The lowermost glandular tubules were well preserved, but at about the middle of the mucosa became transformed into a jumble of cells, many of which contained pycnotic nuclei, others nuclear fragments. The uppermost layer of the mucosa was converted into dull pinkish-staining debris and showed frequent signs of exfoliation of large masses of dead material. The capillaries in the submucosa were richly injected by red cells.

CASES WITH DIFFUSE NECROSIS OF THE LIVER

CASE 4.—History.—A boy, aged 16, who was admitted to the Psychopathic Pavilion, December 24, and died the following day, had complained of "stomach trouble" ten days previously, vomited, and turned yellow, according to the report of members of the family. Two days prior to admission he became acutely ill, excited and delirious. He was admitted in restraint, extremely restless and excited. Jaundice was intense, the tongue foul, the teeth covered by sordes. The patient soon lapsed into coma, and just before death the temperature registered 108 F.

Necropsy.—The body was deeply jaundiced. Hemorrhages were apparent in both upper eyelids, in the mouth and beneath the visceral pericardium and pleura and in the substance of the lungs. The liver appeared to be normal in size, its form was preserved, the capsule smooth, and the substance unchanged as far as the naked eye could detect, except that it was diffusely yellow. The gallbladder contained a very small quantity of thin, light colored bile. The kidneys and gastro-intestinal mucous membrane showed no naked eye alterations other than jaundice of the former. The brain was slightly congested. Cultures from the spleen remained sterile.

Microscopic Examination.—Destructive changes in the liver were so widespread and severe that, in sections stained by hematoxylin and eosin, it was not easy to identify the organ. In sections stained by the method of Van Gieson it was seen, however, that the perilobular connective tissue was well preserved or slightly more cellular than usual, and that it supported intact blood vessels together with large numbers of bile canaliculi, the lining cells of which were apparently only slightly changed. In frozen sections stained by sudan III, individual liver cells or small groups of cells crowded with fat globules were strewn through the periphery of the lobule, an occasional cell being more centrally placed. Otherwise the cells lying between the perilobular connective tissue and the central vein were converted into a mass of structureless material consisting of wrinkled, collapsed and ruptured cell membranes, nuclei in various stages of disintegration, granules of bile pigment, and free red cells arranged diffusely or in minute clumps and streaks.

The epithelial cells in the convoluted tubules of the kidney were swollen, opaque and granular, their nuclei obscured. In practically all the tubules the swelling was such as almost completely to obliterate the lumen. The tufts were bloodless and were composed of collections of nuclei of different shapes and sizes arranged without any semblance of order and lying in a pinkish, opaque matrix. In the cortex small hemorrhages were visible, while near the apexes of the pyramids were large extravasations. The lungs showed innumerable discrete and confluent intra-alveolar hemorrhages; in still other alveoli were dense collections of polymorphonuclear leukocytes. The spleen was congested, and the lymphoid follicles were centrally necrotic.

In some places the mucous membrane of the gastro-intestinal tract was well preserved, in other places it showed necrosis, sometimes involving the uppermost layers, at other times extending to the muscularis. The necrotic portions were represented by pinkish-staining granular debris, scattered through which were glandular remnants, red cells, nuclear granules and an occasional collection of lymphoid cells.

Chemical examination of the liver for phosphorus was negative.

CASE 5.—History.—A man, aged 31, who was admitted to Bellevue Hospital, January 8, and died the same day, was profoundly stuporous and could not be roused. The entire body was deeply jaundiced. The patient's temperature was 103 F., pulse 135. Otherwise nothing could be learned of him.

Necropsy.—The skin was deep saffron yellow, and the visible mucous membranes were intensely icteric. There were numerous hemorrhagic extravasations in the omentum, mesentery and parietal peritoneum, pleurae and lungs, spleen and brain. The kidneys were congested and jaundiced, changes which were shared by other of the great viscera. The mucosa of the gastro-intestinal tract was bathed in yellowish chymelike material, but otherwise revealed no changes to the naked eye. The liver was markedly diminished in size, weighing 1,040 gm. The consistency was slightly softer than normal, the capsule thin, the color an intense saffron yellow with fine nutmeg markings. The gallbladder contained a small amount of blackish green bile and the duodenal papilla was permeable.

Microscopic Examination.—The histologic changes were essentially the same as those described in the previous case, namely, cloudy swelling of the kidneys, hemorrhages into the spleen and lungs, the latter associated with a lobular exudative pneumonia, superficial or diffuse necrotic lesions in the gastro-intestinal mucous membrane alternating with better preserved areas, and almost complete destruction of the liver. Sudan III and Van Gieson preparations showed changes not to be distinguished from those described in the preceding case—preservation of the interlobular connective tissue with its bile canaliculi and blood vessels, scattered groups of fat-containing cells near the edges of the lobules, and complete disintegration of the remaining cells with numerous hemorrhages.

Chemical examination of the liver for phosphorus was negative.

CASE 6.—History.—A man, aged 21, who was admitted to the Psychopathic Pavilion, February 18, and died the following day, had worked Monday, the 16th, according to a statement of his brother. Tuesday he complained of having a cold, and Wednesday he became raving. On admission he was intensely agitated, shouting and resisting all efforts to care for him, trying to bite nurses and attendants. At this time he was slightly jaundiced, but in the succeeding twenty-four hours icterus became extreme.

Necropsy.—In addition to the intense jaundice, there were numerous hemorrhages into the lungs and spleen, and a massive extravasation into the soft tissues around the pancreas. The kidneys were swollen and icteric. The mucosa of the stomach appeared to be atrophic and irregularly congested, but otherwise no changes were apparent to the unaided eye. The liver was greatly reduced in size and weighed 890 gm. It was flabby, but increased in consistency, being almost leathery to the touch. Scattered beneath the capsule and throughout the substance were hundreds of irregularly outlined hemorrhages, between which the liver tissue was ochre-yellow and opaque. The gallbladder contained a few cubic centimeters of thin, light colored bile. The pia arachnoid was congested, but the substance of the brain was apparently normal.

Microscopic Examination.—To describe the histologic changes in this case would be a virtual repetition of what has been said of the preceding two cases, including the necrotic changes in the gastric mucosa and the widespread destruction of the liver lobules, although, in the latter situation, hemorrhages were far more frequent and extensive.

Chemical examination of the liver for phosphorus, antimony, arsenic, mercury and tin was negative. Blood removed at necropsy was injected into guinea-pigs with negative results.

SUMMARY AND CONCLUSIONS

1. There is a variety of epidemic jaundice attended by spontaneous or easily induced hemorrhages in the skin, mucous and serous membranes, viscera, and vari-

ous soft tissues, by mental symptoms ranging from stupor to wild delirium, by clay colored stools, pain and tenderness differing in location and intensity, sometimes by vomiting and diarrhea, with or without elevation of temperature (the latter, when present, being due, apparently, to intercurrent conditions, such as bronchitis and pleuritis) and, finally, by such incidental phenomena as muscular twitchings and itching of the skin. The mortality is high. The disease lasts from a few days to two or three weeks, depending, in large measure, on the extent and severity of the necrotic changes in the liver. In the relatively small number of cases that we have seen at Bellevue Hospital it was noted that those corresponding to acute yellow atrophy of the liver and accompanied by violent mental disturbances occurred in young persons, while the more prolonged cases associated with stupor were found after the fiftieth year of age. All the cases that we have seen were in male patients.

2. Anatomically, in addition to jaundice and hemorrhages, the disease is characterized by cloudy swelling or even necrosis of the tubular epithelium of the kidneys, by cloudy swelling of the liver with or without dissociation of cells and foci of icteric necrosis, or, by widespread necrotic changes corresponding in all essentials to those commonly described as acute yellow atrophy of the liver, and by diffuse or scattered superficial or deep areas of coagulation necrosis in the gastro-intestinal mucosa. In the more prolonged cases, changes in the gastro-intestinal tract are evident to the unaided eye; in the rapidly fatal cases no alterations in this locality are discernible to the naked eye, and it remains for microscopic investigation to disclose them.

3. The disease is not transmissible to guinea-pigs by intraperitoneal inoculation of blood or urine, and is probably not of spirochetal origin, but a manifestation of toxemia of unknown nature. Phosphorus and other heavy metals are not detectable on chemical examination of the necrotic livers. The structural alterations in the gastro-intestinal tract indicate that the provocative agent gains entrance through this channel. The necrotic changes in the liver in those cases that resemble acute yellow atrophy suggest that the toxic substance is absorbed from the gastro-intestinal tract into the tributaries of the portal vein, since the dead liver tissue corresponds quite definitely to the distribution of the portal blood, the lobules being totally destroyed, while the interlobular structures, including blood vessels and bile canaliculi, remain relatively well preserved. Jaundice seems to be due to inability on the part of the bile to escape from its intrahepatic capillaries, since there is no demonstrable obstruction in the larger ducts, microscopically or otherwise. The hemorrhages probably depend primarily on injury to the capillary endothelium brought about by the action of bile salts and encouraged by diminution in fibrinogen due to destruction of liver substance.

4. The association of intense jaundice with clay colored stools, and pain and tenderness in the region of the gallbladder and liver, has occasionally prompted surgical intervention. The occurrence of the disease in epidemic form, and the presence of more or less profuse hemorrhages in or from the skin and mucous membranes, should serve to arouse caution in the interpretation of symptoms that otherwise are suggestive of remediable obstruction to the escape of bile.

400 East Twenty-Ninth Street.

OCCLUSION OF THE RIGHT POSTERO-INFERIOR CEREBELLAR ARTERY

GEORGE W. HALL, M.D.

CHICAGO

The literature on the subject of occlusion of the postero-inferior cerebellar artery records the fact that the syndrome brought out by occlusion of this vessel corresponds very closely to that found in occlusion of the vertebral artery. Occlusion of the basilar artery may also produce a similar syndrome.

The patient whose history and symptoms I record has in the main recovered from the attack, so that the clinical diagnosis cannot be verified.

Breuer and Marburg¹ show that clinically and experimentally the differential diagnosis between occlusion of the postero-inferior cerebellar artery and the vertebral artery cannot be made with certainty. In one of their cases the vertebral artery was occluded and the postero-inferior cerebellar artery escaped, and yet the lesion occupied about the same region as in cases in which the postero-inferior cerebellar artery was occluded. If pontile symptoms are present, according to these authors, the vertebral artery rather than the postero-inferior cerebellar artery is probably the seat of the lesion.

REPORT OF CASE

History.—S. M., man, aged 35, chauffeur, referred to me by Dr. H. G. Dern, Nov. 25, 1919, said that while on his way to work about October 1, he suddenly became dizzy and fell to the ground, but did not lose consciousness. He was taken home and put to bed. When Dr. Dern first saw him he said he had vomited several times during the day. On examination at that time the physician observed the presence of a horizontal nystagmus; also when the patient attempted to bring a glass of water to his mouth with his right hand, marked ataxia was present. He had similar ataxic movements of the right leg on attempting to walk. There were no such movements of the left arm or left leg. The patient was hoarse and talked almost in a whisper for a period of four or five days. There was no dyspnea. The pulse, however, was very slow for several days.

About one week after the onset of the attack the patient noticed while walking along the sidewalk there was a constant tendency to deviate to the right, and before he realized it he was off the sidewalk. The dizziness improved, the ataxia got better, the vomiting ceased, and at the end of ten days or two weeks the patient was walking around the house and was feeling very well, as he expressed it. His condition then remained stationary until November 15, when while taking a walk he suddenly became dizzy and would have fallen had not an adjoining wall supported him. He was able to get back upstairs alone. His dizziness gradually improved until November 25, the date of his entrance to St. Luke's Hospital.

There was no history of any previous illness. He had never undergone any surgical operation. He denied syphilis or other venereal infection. His family history was entirely negative.

Examination.—I found the head slightly tilted toward the right. The patient had a tendency to go to the right when walking. Both pupils reacted to light and accommodation. The right pupil was smaller than the left. The palpebral fissure on the right side was narrow, and an apparent enophthalmos was present on the right side. Horizontal nystagmus was present but not marked. The optic disks were normal, and no other ocular paralysis was observed. There was no deafness. The facial muscles on the right side showed slight weakness, but were apparently normal on the left side. There was no deviation of the jaw on opening the mouth. On protruding the tongue there was noticeable a slight atrophy of the right side of the tongue. The palatal muscles and the larynx were negative. There was no lagging of either vocal cord. The heart action was normal. The respiratory tract was negative. The deep reflexes were normal except that the right knee jerk and the right Achilles were slightly decreased. The abdominal reflexes were present but decreased. The sensory findings showed a loss of pain and temperature sense and to a less extent tactile sense on the right side of the face, corresponding to the distribution of the sensory portion of the fifth nerve and more pronounced over its upper branches. There was a patch of herpes at the edge of the right naris. The right side of the

face did not perspire, while the left side showed a profuse perspiration. A pin prick caused bleeding on the left side of the face very easily, indicating a vasomotor disturbance. There was no disturbance of sensation on the left side of the face. Posteriorly over the scalp, the region supplied by the cervical plexus on the left side, sensation was dull to the pin prick. Beginning in the region of the clavicle and involving the entire left side of the body there was a loss of pain and temperature sense only. The tactile and position senses were preserved on both sides of the body. There were no bladder or rectal disturbances. The systolic blood pressure was 120, diastolic, 80. The Wassermann reaction was negative with both blood and spinal fluid. The vestibular apparatus was carefully tested by Dr. Frank Brawley, who reported:

"Complete test of the vestibular apparatus indicates a lesion of the right side of the brain stem, which almost completely blocks the responses from the horizontal and vertical canals and both raphe of Deiter's nucleus. There are disturbances in the responses from the left side also, probably due to pressure. The areas involved correspond to the location of the postero-inferior cerebellar artery, but cover a greater area than Louis Fisher's² case."

COMMENT

While no definite etiology is given in this case, Salmon³ states that 88 per cent. of the cases of thrombosis of the postero-inferior cerebellar artery occur in alcoholics or syphilitics. The characteristic symptoms, as stated by this author, include those recorded in this case. He also makes the statement that the symptomatology caused by thrombosis of the vertebral artery is analogous to that of thrombosis of the postero-inferior cerebellar artery. In one case he noticed disturbances of deglutition and paresis of the facial

Areas (indicated by shading) in which there was loss of the sense of pain and temperature.

3. Salmon, A.: *La trombosi della arterie bulbari*, *Riforma med.* 29: 649, 1913.

muscles on the side of the lesion, transitory diplopia, and especially the sympathetic syndrome, as shown in this case, namely, enophthalmos, and narrowing of the pupil and of the palpebral fissure on the side of the lesion.

Spiller⁴ has recorded the same syndrome, and states that it is not present in all cases.

A perusal of the literature discloses no previous reports on the testing out of the vestibular apparatus, except by Fisher, as stated in Brawley's report. In Fisher's case there is shown involvement of the horizontal canals without involvement of the vertical canals. He arrives at the conclusion that the anatomic arrangement is such as to bear him out in the statement that the normal connections leading from the horizontal canals to the vestibular apparatus through the inferior peduncle to the cerebellum are blocked, whereas the fibers from the vertical canals through the middle cerebellar peduncle to the cerebellum are not damaged.

In studying the symptoms from the standpoint of cranial nerve involvement, we find that the sensory portions of the fifth, sixth, seventh, eighth, ninth, tenth, eleventh and twelfth nerves have all been recorded in one report or another as having been involved, but not all have been involved in any one case. The spinal or sensory root of the fifth nerve on the side of the lesion has been involved in every case reported. That the sixth nerve, when involved, usually shows a transitory involvement, as evidenced by the temporary diplopia, and the paresis of the face on the side of the lesion, has been noted in a few instances. Vestibular symptoms due to involvement of those fibers entering the inferior peduncle especially are present in all the cases reported. Difficulty in deglutition, transitory in some cases and persistent in others, is very common. Paresis of one vocal cord producing temporary hoarseness may be present, and slowing of the pulse, most frequently transitory, has also been noted in a few cases. Slight hemiatrophy of the tongue on the side of the lesion, as shown in this case, has not, so far as I can learn, been previously referred to in the literature. However, Wallenberg⁵ speaks of a slight paresis of the hypoglossal due to a lesion in the most laterally situated roots of the hypoglossal nucleus.

The sympathetic syndrome is a common symptom, and can be explained on the location of those fibers in the medulla which are in close proximity to those for pain and temperature, and are also situated near the spinal root of the fifth nerve in the dorsolateral portion of the reticular substance. The fibers for the tactile and position sense are more laterally located in this region and consequently escape injury.

It might be well to add by way of explanation that the fibers for pain and temperature sense located in this region of the medulla supply the opposite side of the body, which accounts for the clinical distribution of such disturbances.

The ataxia, vertigo and asynergy are cerebellar in character and consequently homolateral, owing to the constant involvement of the inferior cerebellar peduncle and Deiters' nucleus, which have to do with equilibrium through the spinal and vestibular connections with the cerebellum.

Wallenberg states that when difficulty of deglutition is present and persistent, both the vertebral and inferior cerebellar arteries are involved, while transitory paral-

ysis of deglutition may be caused by involvement of the postero-inferior cerebellar artery alone. He injected the postero-inferior cerebellar artery and traced its course. He found that frequently there is only one postero-inferior cerebellar artery, and then it is usually the left. Several smaller arteries take the place of the missing cerebellar artery in such instances, and a large antero-inferior cerebellar artery replaces the missing posterior cerebellar artery.

While cases presenting the symptoms usually observed in occlusion of the postero-inferior cerebellar and posterior vertebral arteries are not so uncommon, yet at the same time the cases are so rare that the attention of the general practitioner is not attracted in a way to impress him with the frequency of this syndrome.

CONCLUSION

1. There is a constant syndrome producing disturbances in sensation over the distribution of the fifth nerve on the side of the lesion, with disturbances of the pain and temperature sense on the opposite side of the body.
2. There is a definite sympathetic involvement of medullary origin producing enophthalmos, narrowed pupil and narrow palpebral fissure on the side of the lesion.
3. In some cases the symptoms are more widespread than in others, as in this case, and present a slight hemiatrophy of the tongue on the side of the lesion.
4. Examination of the vestibular apparatus reveals certain definite localizing symptoms on the side of the lesion.
5. The occlusion of the postero-inferior cerebellar artery and the vertebral artery may present practically identical symptoms, so that clinically one cannot be sure whether he is dealing with an occlusion of one or the other artery.

VENEREAL CAMPAIGN IN PARIS, DISTRICT OF THE AMERICAN EXPEDITIONARY FORCES

JOSEPH EARLE MOORE, M.D.

BALTIMORE

Since the cessation of hostilities, numerous papers have appeared¹ dealing in general and in particular with the results obtained in the venereal disease campaign in the American Expeditionary Forces. Nowhere was there a graver problem to be faced, and nowhere were more interesting results achieved than in Paris, the Mecca of every American in France.

The Paris district included the city of Paris itself and the country included in the province of Seine et Oise, which completely surrounds Paris, an area, roughly, of 400 square miles. Until January, 1918, Paris was the headquarters of the service of supply, with a permanent strength of from 2,000 to 4,000 men. In spite of the fact that the headquarters of the service of supply was moved to Tours in January, the permanent personnel of the district grew apace.

with the American Expeditionary Forces at large, until, for the latter half of 1918 and early part of 1919, it averaged from 17,000 to 22,000 men. About one half of these men were stationed in Paris proper, the other half in the immediate environs or the surrounding country. No point in the district was farther away from Paris than 30 miles: the city was therefore easily accessible to all.

In addition to the permanent personnel there was always a large floating population of troops of the American Expeditionary Forces made up, until after the armistice, of casualties en route through the city, men absent without leave, and during the two months of the Marne-Vesle battles, about 1,000 men a day on short leave from the six American divisions at the front. Jan. 22, 1919, three days' leave to Paris was formally opened. Thereafter, an average of 1,500 men arrived daily. No accurate data are available as to the exact census of casualties in Paris, but it was estimated by the provost marshal that the daily floating population after July, 1918, was between 5,000 and 10,000.

Until March, 1918, no organized plan for handling the problem in Paris existed; and the inevitable result was an appallingly high rate per thousand, as shown in the accompanying chart. It can probably be said without fear of dispute that the rate of 480 per thousand troops, attained in January, 1918, was the highest ever reached in any part of the American Expeditionary Forces. In March, 1918, the plan of organization devised by Col. Hugh H. Young, senior consultant urologist to the American Expeditionary Forces, of placing with each combat division a trained urologist to care for the prevention and treatment of venereal disease, was extended to other areas of France, particularly the service of supply, and I was appointed urologist to the district of Paris.

METHODS OF FACING THE PROBLEM

The available methods of attack with which to face the problem were:² (1) to diminish the number of contacts by placing out of bounds houses of prostitution and areas frequented by street-walkers; (2) to cooperate with the French in the detection and treatment of infected women; (3) to eliminate, so far as possible, the factor of alcoholism by placing out of bounds cafés which sold liquor to Americans; (4) to make use of all measures of social hygiene in an effort to diminish contacts; (5) to provide, by means of a sufficient number of adequately staffed prophylactic stations, sufficient opportunity for the prevention ("early treatment") of venereal disease; and by careful physical inspections of all troops, for its early detection; (6) court martial for all men having contracted a venereal disease, and, (7) treatment of disease with the organization so that as little time as possible would be lost from military duties; and at the same time, segregation of all infected patients, to prevent the further spread of infection.

REPRESSION

The primary object of any military venereal disease campaign is, of course, to cut off infection at the source by diminishing contacts. The most effective measures to accomplish this are the first three just outlined. In Paris, however, these measures were utterly out of the question. Prostitutes were present

in enormous numbers, and were, as a rule, exceedingly aggressive. They preferred Americans to the soldiers of any other nation because of the higher pay which the doughboy received. There are few houses of prostitution, about forty in all, with a total of only 400 inmates. The overwhelming majority of the estimated 75,000 prostitutes in Paris are street-walkers, either professional or clandestine. All women in houses are licensed by the police and inspected bimonthly by police physicians (a method which, as Flexner³ and later observers have demonstrated, does not decrease the risk of infection); of the street-walkers only about 5,000 are licensed and inspected. The remaining 70,000, including practically all the clandestine prostitutes, are without supervision or control of any sort, and are permitted to remain undisturbed by the police so long as they are not too publicly offensive. Solicitation is the rule, and is carried on much more publicly than anywhere in this country. There are about 2,500 small hotels, any of which, as well as some of the more expensive and fashionable, are available as houses of assignation.⁴

Identification by a soldier of the source of his infection was in practically every case impossible, since usually he did not discover the name or address of his partner. So far as alcohol was concerned, the situation was precisely similar to that of prostitution. Many of the city's several thousand cafés were designated as out of bounds by the provost marshal, but no number of military police would have been sufficient to enforce the order. It may be considered that alcohol in any form was freely accessible to those who wanted it. Even under these "wide open" conditions it is felt that the use of alcohol played little part in the incidence of venereal disease among Americans.

It was at once apparent, then, that contacts could not be decreased by repression, as had been done with such remarkable success elsewhere in the American Expeditionary Forces, notably at some of the base ports.² It was useless to place houses of prostitution out of bounds, when such an abundance of prostitutes flourished on the streets. One could not designate certain streets or areas as forbidden to Americans because every street, no matter how small or how distant from the center of the city, was used by these women. In the same way, hotels and cafés could not be placed out of bounds, because, with very few exceptions, every hotel in Paris was available for use by couples without baggage, and every café was willing to sell whisky to Americans.

SOCIAL HYGIENE AND DISCIPLINARY MEASURES

Since it was impossible because of the circumstance of location to employ these powerful weapons, we were forced to rely, for the purpose of diminishing contacts, on measures of social hygiene and on the application of such disciplinary measures as could be accomplished. In March, 1918, the campaign was begun, with results that are strikingly shown in the accompanying chart. Within three months the incidence rate per thousand had been cut almost in half.

In the chart the annual rate per thousand was estimated by dividing the number of cases during a given period by the number of men in the command (which

3. Flexner, Abraham: *Prostitution in Europe*, New York, Century Company, 1914.

4. Robinson, Daisy M.: Personal communication to the author. Dr. Robinson carried out during 1918 a most extensive investigation of the situation in Paris, and I am indebted to her for full and accurate data regarding the matters in this paragraph.

2 Young, H. H. (Footnote 1).

gave the rate for the period only, not for the year), and then by multiplying this result by the fractional part of a year which the period represents. Thus, if four cases occurred among 1,000 men in one month, the monthly rate was 4 per thousand, but the annual rate was 48 per thousand. From November, 1917, to December, 1918, the rate was computed by the month; thereafter it was computed by the week.

The period from November, 1917, to March, 1918, illustrates the high incidence rate attained when no special campaign was in force; the drop in the rate to one-half its previous figures in June, 1918, illustrates the results obtained when the measures inaugurated in March had begun to tell. The preliminary rise in May, 1918, is due to the uncovering of additional cases by active enforcement of the physical inspection order. There is a sustained level at about 110 per thousand, with a gradual rise at and following the armistice (November, 1918). The further lowering of the average rate during 1919 to about ninety-five per thousand is due to increased facilities for and more care in administering prophylaxis. The peaks of January 16, February 19, March 19, and April 9 are the results of pay day.

The factors which accomplished this decrease in the rate are worth detailing briefly. A campaign of education was begun, consisting of lectures to men and officers, and the liberal use of the U. S. Public Health Service film, "Fit to Fight." Lectures to the men were repeated until they had been told of the various military angles of venereal disease by medical officers, line officers, and most important of all, trained noncommissioned officers, who were better able to reach the level of the men than the average officer. It was found, with much surprise, that an overwhelmingly large proportion of the men had received no instruction whatever on the venereal disease question before coming to France.

Through the cooperation of the various relief organizations, chiefly the Young Men's Christian Association, the Red Cross and the Knights of Columbus, efforts were made to provide enough recreational activities for the men to keep them off the streets. By the time the armistice was signed; the Y. M. C. A. alone had, in addition to its various canteens and hotels for officers and enlisted men, three large halls, capable of accommodating 14,000 men, in which vaudeville, moving pictures, boxing matches, dances, etc., were given nightly.

These measures accomplished something, but not enough. Many soldiers, even though thoroughly instructed in venereal disease matters and fully provided with the opportunity of Y. M. C. A. and Red Cross entertainment, were obstinate in preferring the society of women of the Paris streets. For this class, it was necessary to institute disciplinary measures.

This was complicated by several factors: 1. The soldiers in Paris were, for the most part, soldiers in name only, since most of them were highly skilled office or technical workers, whose day was entirely taken up by routine duties, uncomplicated by drills or other military inconveniences. Thus they were as a whole unaccustomed to and intolerant of restrictions or discipline. 2. They were divided into small detachments, often commanded by officers whose prime interest was technical work, who came into contact with their men only during office hours, and who, being uninterested in discipline for themselves, were careless of the welfare of their men. As a result of this, the general custom was that after the day's work was done, the soldier's night belonged to him, to do with as he would. 3. Detachments were widely scattered in various large or small barracks, so that just after the armistice, 125 detachments lived in fifty-two different places. As for the floating personnel, they were usually left entirely to their own resources and were wholly beyond the reach of officers or discipline.

Owing to these facts, the "all night leave," with its consequent multiple exposures and failure to use pro-

phylaxis until from twelve to fourteen hours after the first intercourse, was a tremendous evil. In June, 1918, over one half of all prophylactic treatments were taken after all night exposures. The question then became one of preventing men from being on the streets all night. In those camps or barracks situated outside the city, the commanding officer was requested to allow his

Annual venereal disease rate per thousand troops, Paris district of the American Expeditionary Forces, from November, 1917, to April 23, 1919.

men leave to Paris only once a week, and to insist that they return by midnight. In the city itself, all troops were required to be in their barracks by 9 p. m., unless furnished with a pass to visit a designated place of amusement. Enforcement of these seemingly stringent measures was accomplished by roll calls in all barracks, when every man must be present or accounted for, and by the cooperation of the military police, who were required to examine passes of all men found on the streets after 9 p. m. Rigid enforcement of General Pershing's admirable General Order 77, 1918, was insisted on, especially those points relating to the questioning of all men returning from pass by a guard as to exposure, with compulsory prophylaxis if exposure was admitted, and compulsory prophylaxis without regard to exposure if a man returned intoxicated.

Every effort was made to stimulate a feeling of organization pride and competition. A copy of the weekly venereal disease report was sent to the commanding officer of each organization, with the request that it be posted on the bulletin board where all ranks had an opportunity to see "just where their outfit stood." When all of these methods failed, and an organization had a persistently high incidence rate,

recommendations were sent to the commanding general that all pass privileges for its men be suspended for a given period. This was frequently done with a most salutary effect. With several detachments of negro troops situated outside the city, it was found necessary to adopt the measure instituted by Col. George Walker at one of the base ports—that of compulsory prophylaxis for every negro soldier each time he reentered the camp after leaving it, without reference to whether or not he admitted exposure.

Bimonthly physical inspections were thoroughly carried out, in conjunction with the district dermatologist. A great deal was accomplished by these means. The rise in the rate for May, 1918, shown in the chart, is directly due to an increase in the number of inspections and to more care used in making them.

All of the disciplinary measures outlined failed somewhat in the accomplishment of their purpose so long as troops remained widely scattered in small detachments. The length to which this practice had gone is exemplified by one organization, whose 150 men were quartered in twenty-five different places all over the city. The remedy for this was concentration. The ideal solution would have been one large camp, in which all men and officers could be quartered. Unfortunately, for many reasons, the ideal or anything closely approaching it was wholly impossible. Some progress was nevertheless made, in spite of seemingly insuperable difficulties, and by February, 1919, about 10,000 men (approximately one half of the strength) had been concentrated in eight large barracks. In all of these places it was possible to institute proper pass regulations to obviate the "all night evil," and to insure prompt administration of prophylaxis.

PROPHYLAXIS

When the incidence rate had reached a stationary level at about 110 per thousand, it became obvious that exposures could not be decreased much below this point, no matter what social and disciplinary measures were applied. Matters would have thus stood at an impasse had it not been for prophylaxis. The feeling grew that if prophylactic treatment could be made more efficient and more widely available, and that if more men could be persuaded or forced to use it, the rate could be still further lowered. Moreover, for the large group of casuals and leave men, none of the foregoing measures were applicable, and from the first our whole reliance had perforce to be placed on prophylaxis.

In order to make the treatment easily available, stations were opened in every barracks which housed more than fifty men, in the two officers' hotels, all the Y. M. C. A. and Red Cross hotels used for casuals, and in a large building centrally located near the Opera and especially rented and equipped for the purpose. Knowledge of the location of the stations was disseminated to permanent troops through bulletin boards, and to incoming casual troops by cards distributed at all the railroad stations, which cards also contained warnings of the prevalence and danger of venereal diseases and advised continence as the only sure preventive. All military police on street patrol were furnished with a complete list of stations, and each man required thoroughly to familiarize himself with the location of the station nearest to his beat, so that inquiries could be promptly and properly answered. The magnitude to which this work grew can be seen by the fact that in March, 1919, there were in the

district seventy-two prophylactic stations, which gave a weekly average of 5,000 treatments. I have at hand the statistics of 95,916 treatments given in a period of a little more than twelve months.

The number of stations being sufficient to care for all needs, the quality of the treatment administered was the next point to be considered. All attendants were carefully trained, and their records of successes and failures were checked up weekly. Daily inspections of all stations were carried out by a sergeant, and weekly inspections by a medical officer. The results obtained with their bearing on the venereal disease rate will be fully discussed in another communication.

The application of these measures reduced the incidence rate from a high point of 148 per thousand on January 16 (due to the general rise throughout the American Expeditionary Forces after the armistice), to an average level of 94.6 per thousand for the next fourteen weeks (to April 23, beyond which point I have no figures). The rate for the Paris district after June, 1918, was consistently about four times as high as that for the American Expeditionary Forces as a whole, but was only very slightly higher than that for the regular army in time of peace. Considering the unparalleled situation of our troops in Paris, their freedom from the censorious eyes of home surroundings, and the greatly increased facilities for sexual contact over any other location in France or in this country, the record seems very satisfactory indeed.

TREATMENT

Regarding the treatment of venereal disease in the district, there remains but little to be said. It was impossible to carry out the general plan as originally outlined for combat organizations, of having all patients treated by the organization medical officer, for the reason that most of the organizations in Paris were too small to have a medical officer. For this and other reasons, it was thought advisable to centralize the handling of these cases in the district. In March, 1918, a dispensary was opened in the attending surgeon's office. This rapidly grew to a tremendous size and necessitated expansion of space, which was provided by the Red Cross in American Red Cross Military Hospital No. 9. This hospital was the only one in the American Expeditionary Forces devoted entirely to the handling of venereal (and skin) disease. It contained only seventy beds, by far the largest part of the service being ambulatory. The skin service was combined with it, and the dispensary end grew to the size of approximately 500 patients (300 venereal and 200 skin) daily, requiring the service of sixteen medical officers and fifty enlisted men. In the venereal disease outpatient clinic, during twelve months of which I have record, almost 4,000 new patients were seen, thus divided: gonorrhea, 1,667; chancroid, 485; syphilis, 490; nonvenereal, including other types of genitourinary diseases, 1,126, making a total of 3,968.

It was possible by this means to treat practically all of the venereal disease in the district without loss of time from duty, and with more satisfactory therapeutic results than are ordinarily obtained in civilian dispensaries at home, since the patients, being under military control, were forced to return for further treatment whether they desired it or not. The only drawback to this system was that the segregation of infectious cases was not possible except in the case of primary or secondary syphilis, in which an effort was made to hospitalize the patients until they were no longer infec-

tious. As regards the methods employed in treating venereal disease, they were the same as those used elsewhere in the American Expeditionary Forces and are fully detailed in the "Manual of Military Urology."⁵

CONCLUSION

1. By the use of social hygiene and disciplinary measures, the annual venereal disease rate of the Paris district of the American Expeditionary Forces was reduced from an average level of 313.5 per thousand (for the first five months during which no special steps were taken to combat the evil) to a level of 142.4 for the following nine months. If the first two months of this second period are disregarded, since this length of time was necessary for any measures to take effect, the average rate was reduced to 113.6.

2. This figure (113.6 per thousand) represents the lowest level attained by the repressive and substitutive measures outlined. However, during the next four months, by extending the use of, and improving the quality of, prophylactic treatment, a further reduction to an average level of 94.6 per thousand was accomplished, in spite of the fact that during this period the rate throughout the American Expeditionary Forces at large was gradually rising.

3. It is hoped that the various methods employed may prove useful to medical officers in charge of the health of troops, especially when stationed in large cities. Certain of the points mentioned will suggest themselves as available in a campaign against venereal disease in civil life.

NERVE DEAFNESS DUE TO CONGENITAL SYPHILIS IN THREE CHILDREN

M. B. KAY, B.S., M.S., M.D.

Pediatrician, Presbyterian Hospital

PITTSBURGH

Deafness, or partial deafness, is being more and more often ascribed to syphilis. Inherited or congenital syphilis in infancy and childhood attacks the eighth nerve with great frequency.

The cases reported herewith are remarkable not because syphilis has produced deafness, but because it has attacked all the children of this family in the same manner, every other part of the body escaping except the eighth nerve.

Though the mother has had four self induced abortions (all abortions coming after the birth of these children), the three children were perfectly healthy children at birth, having none of the stigmas of syphilis and they continued so until at least the end of the first year. Owing to the fact that at least a year had elapsed before signs of deafness developed, these are undoubtedly cases of "late hereditary syphilis," and illustrate the accepted idea of the occurrence of deafness late in the disease.

So far as the parents know, no case of deafness had appeared in their families prior to the birth of these three children. The family history is not remarkable except for the important fact that the father admits a genital sore twelve years before. (At first he denied all venereal history.) This sore was treated locally,

no internal medication having been given. He denies ever having had a skin eruption. The mother and father both show ++++ Wassermann reactions.

The mother, who, when I first saw her, informed me that she had suffered much from "rheumatism in the chest and sciatica," has since been put on antisyphilitic treatment and has been entirely relieved of what she considered very distressing symptoms.

REPORT OF CASES

CASE 1.—*History*.—I. R., girl, aged 7, born by spontaneous delivery at full term, was healthy at birth, no blemishes were noted, and she weighed between 7 and 8 pounds. She was breast fed until the fifth month, after which she did poorly on a proprietary food. At 1 year she sat up, and at 16 months walked and talked. She "was like a natural child until the nineteenth or twentieth month, and then went back." Otitis media appeared at the seventh month, and pertussis at 4 years. The present illness dates from the nineteenth month, at which time the baby began to point to objects and would no longer pay any attention when spoken to or take any notice of noises. This apparent failure to hear has persisted to the present time.

Examination.—The patient was fairly well developed and apparently mentally alert, but was unable to hear sounds of any sort. She spoke no words, but could write all the letters of the alphabet in large print, though she could not write them in order. The epitrochlear glands were enlarged on the right side, but otherwise the findings were not remarkable. The patient was 47½ inches tall and weighed 39½ pounds. Sept. 10, 1919, the result of a blood Wassermann test was ++++.

CASE 2.—*History*.—E. R., girl, aged 5, born by spontaneous delivery at full term, and breast fed until the ninth month, had pertussis at 2 years, but no other diseases of childhood. She sat up at 7 months, and walked at 13 months, up to which time she was apparently a normal baby. At 13 months, "she seemed to go back and could do nothing." She was never well nourished from this period, and the present illness dates from the thirteenth month. Her history from this point on resembles that of Case 1.

Examination.—She was a fairly well developed child, 43 inches in height, weighing 38½ pounds, and mentally alert. She made known all her desires by motions and sounds, and spoke no words.

CASE 3.—*History*.—G. R., boy, aged 4 years, born by spontaneous delivery at full term, weighed 7½ pounds, was healthy at birth, and was breast fed until the ninth month. He had pertussis at 1 year, the only disease of childhood. He sat up at the sixth or seventh month, walked at 12 months, and could apparently hear at the age of 1 year. He was "like any other child until 1½ years old," after which time he made no progress so far as speech was concerned.

Examination.—The patient was fairly well developed, and mentally quite alert. He did not talk, but made signs quite intelligently, and could carry on a sign language with his sisters. The pupils reacted to light and accommodation normally. He could hear a very loud sound, but paid no attention to ordinary or loud conversation.

TREATMENT AND RESULTS

Each of these children was put on ascending doses of potassium iodid. Jan. 13, 1920, each child was taking 35 grains, three times a day. All of them were having the expected nasal discharge produced by the drug. One half grain of mercury with chalk, three times daily, very promptly caused gastric distress and was stopped for the time.

All three children were brighter and were beginning to hear loudly spoken words. All could hear the ticking of a watch at a few inches; this they could not do when first seen. All were beginning to talk, using such words as mamma, papa, yes, no, pie, and a few others; and they were learning new words rapidly. When

⁵ Young, H. H.; Keyes, E. L., Jr., and associates: Manual of Military Urology, Paris, Masson et Cie, 1918.

spoken to in a fairly loud tone, the children immediately paid attention, showing that they could hear. The first patient had grown $\frac{1}{2}$ inch and had gained 5 pounds. The second patient had grown $\frac{1}{2}$ inch, and gained $3\frac{1}{2}$ pounds. The third patient had grown $1\frac{1}{2}$ inches, and gained 4 pounds.

The general result has been good, but the question that must be answered to the parents is, What will be the final result? I believe that little may be promised as to the recovery of the sense of hearing. Such patients show slight improvement if any, an irremediable damage having already been done by the time these patients are brought to one's attention. Further care of these children should provide for their education in a proper institution. They will also be put on inunctions of mercury, and the routine antisypilitic treatment will be continued to the time when repeated Wassermann reactions cease to be positive. I believe it advisable to continue potassium iodid beyond this point, the guide, of course, being the improvement or failure of the sense of hearing.

SEVERE MERCURIAL STOMATITIS CAUSED BY THE ADMINIS- TRATION OF CALOMEL

REPORT OF TWO CASES

ARCHIE EWING GORDIN, M.D.

Attending Surgeon, Mississippi State Charity Hospital

JACKSON, MISS.

During the last two months two severe cases of mercurial stomatitis have come under my observation: an acute case, and a case of thirteen years' standing, showing the result after recovery. At this time it seems especially appropriate to report these cases, as calomel is being extensively used as a routine cathartic, though many eminent therapists are advising against its routine use.

REPORT OF CASES

CASE 1.—History.—W. H., a white man, aged 50, a farmer, whose habits were good, and who had always enjoyed good health except for the usual diseases of childhood, had malaria in 1916. He had been slightly salivated on several occasions after taking calomel. Oct. 25, 1919, he felt bad and was constipated. He took several cathartics, such as castor oil and magnesium sulphate. These did not give him the proper relief, so he concluded he was "bilious," and took two "liver pills," not knowing that they contained 1 grain of calomel each. The patient stated that he would have taken calomel, but he remembered the disagreeable salivation which he had noticed several times before. The pills did not have the proper effect, but on the following day he became salivated, saliva dropping from the corners of his mouth. This was followed the next day by an increase in salivation, but the patient, having work to do, was out in the rain for several hours. On the third day his gums and tongue became very painful, and saliva poured from each side of his mouth. Feeling very weak, aching in every joint and somewhat nauseated, he became alarmed and summoned a physician. On this day I was called in consultation, and found the patient very much weakened; severe diarrhea, aching in joints, and soreness of the mouth were his chief complaints. Saliva was dripping from the mouth. There were two black gangrenous streaks, one on each side of the tongue, and several black gangrenous areas on the inner sides of the gums. The entire tongue and mucous membranes were much inflamed. On the fourth day the black streaks on the tongue

were increasing, and several small gangrenous areas were noticed on the buccal mucous membrane. The throat was red and swollen, and the patient showed marked tenderness over the jaws. The odor from the mouth was exceedingly offensive.

The only treatment that had been given was a mouth wash with compound solution of sodium borate (Dobell's solution) at frequent intervals.

Examination.—The patient was sent to the Baptist Hospital, where an examination revealed no signs of any physical disability other than the foregoing. Examination of the blood was negative for malaria. The blood count revealed: white cells, 8,000, with 64 per cent. polymorphonuclears and 36 per cent. small lymphocytes; the Wassermann reaction was negative. The specific gravity of the urine was 1.013; there was a slight ring of albumin and there were a few granular casts.

The temperature ranged from 97.6 to 98.6 F., being subnormal most of the time. Diarrhea was present throughout the disease, and salivation persisted till death. The pulse was very weak and irregular during the last three days.

Treatment and Course.—The gangrenous areas were cauterized with 50 per cent silver nitrate solution; eliminative treatment with magnesium sulphate was begun, as was also stimulative treatment with strychnin and digitalis. The patient was put on a soft diet. This treatment was continued throughout the illness, except that chromic acid was used at intervals in place of the silver nitrate to cauterize the gangrenous areas. Cauterization was carried out twice a day.

On the fifth day the gangrene continued to spread, involving the entire upper and lower gums, with several gangrenous spots on the soft palate. The condition became progressively worse; there was gangrene of nearly the entire inner surface of the mouth, and the teeth became loosened and painful to the touch. The patient's general condition also became very grave, with a rapid, irregular pulse, weakness and complete loss of appetite; he became very restless and finally sank into semiconsciousness and died on the seventeenth day.

During the course of the illness, especially during the last few days, large gangrenous sloughs came from the inner surface of the mouth, sometimes hanging down into the esophagus, causing the patient almost to strangle. Before his death the only tissue in the mouth that was not gangrenous was a small strip in the middle of the tongue, about 1 by 6 cm., posteriorly. The gangrene was moist, and extended deep into the tissues underlying the mucous membrane.

CASE 2.—History.—L. G., a white man, aged 18, a farmer, of moderate habits, had had malaria when he was 5 years old, and his physician gave him a dose of calomel. The following day he became severely salivated. His condition became progressively worse, with weakness, diarrhea, salivation, and finally gangrene of the entire inner side of mouth. This condition lasted about three weeks, at which time the patient began to improve, and by the end of two months he was able to get out of bed. During the course of the illness his mouth was extremely sore and inflamed, with a profuse saliva. Nearly the entire right cheek sloughed away, and all but one or two teeth became loosened and fell out. The patient gradually improved, but because of soreness was unable to open his mouth. Later, scar tissue formed, making it impossible for him to open his mouth at all. From the time of his recovery till the present time he had fed himself through a small space, where a tooth had fallen out.

Examination.—On entrance to the Charity Hospital, the patient was poorly nourished and poorly developed. There were no physical disabilities other than the following: The patient was unable to open the mouth at all. On the right side of face there was a hard scar, circular in outline, involving the entire right cheek. It was adherent to the bony structures underlying it. There seemed to be bony union between the inferior and superior maxilla on the right side. The condition of the condyles could not be determined, as the scar made any motion of the condyles impossible. The inner side of the mouth could be seen only by passing a cystoscope

through the space left by the absence of a tooth. The exact condition could not be made out, but there seemed to be very little mucous membrane left, there being an excessive amount of scar tissue in all parts of the mouth. The tongue appeared normal. Roentgenographic examination revealed a bony formation between the upper and lower jaws on the right side, but did not show the condition of the condyles satisfactorily.

Operation and Findings.—A plastic operation was performed to cover up the cheek and to get motion in the jaws. Only the pathologic condition will be described here, as it is too early to give the end-results of the operation. I may say here, however, that after operation the mouth could be opened to the extent of about 1 inch. A flap from the neck was turned upward to cover the defect in the cheek. Mucous membrane was transplanted in various places in the mouth.

There was a very ugly formation of scar tissue, taking in the entire right side of the cheek and firmly attached to the bony structures underlying it; the lips and corner of the mouth on the right side were absent. The mucous membrane on the under surface of the lips was gone, and the lips were adherent to the gums. Thick scar tissue held the mouth firmly closed. The entire buccal mucous membrane had been replaced by scar tissue. The tongue was bound to the floor of the mouth by bands of scar tissue.

The inferior and superior maxillary bones were strongly united by bony union. The floor of the right antrum had entirely sloughed away, the inferior maxilla forming its floor. A few teeth still remained in front, the right lower canine, one bicuspid and the right upper first molar. These were very much distorted and did not come in contact, but overlapped and pressed firmly against the opposite gums. The condyles were not involved.

COMMENT

These are the two most severe cases that have come under my observation in a relatively short time, though a number of milder cases of salivation have been seen. It surely seems time for general practitioners to take these conditions into consideration and to discontinue the promiscuous use of calomel as a cathartic.

I believe I am safe in saying that calomel is misused more than any other drug, especially in the Southern States. There are certain sections in the South where calomel is used in 90 per cent. of all diseases. Many practitioners continue to administer calomel for its effect on the liver, in spite of the fact that all standard textbooks on pharmacology teach that it has no action on this organ. As recently stated: "Calomel, being insoluble in the mouth and the stomach, passes through without affecting them in transit. . . . As soon as the calomel enters the intestine, it is attacked by the alkaline pancreatic and intestinal juices, which decompose it into mercury and yellow mercuric oxid. The latter dissolves slowly and incompletely in alkaline intestinal fluid. The small quantity of mercuric ions thus liberated excites peristalsis. . . ." We are certain now that the action of calomel as a cathartic is simply a mechanical irritation due to the metallic mercury liberated, and that it has no action on the liver.

In the South calomel is widely used, every family using it, every druggist prescribing it, and, unfortunately, the majority of physicians using it, and allowing the laity to labor under the wrong impression that it cleans the liver in "bilious disorders" (this term being applied when no other diagnosis is made). We as physicians should strive to correct this false impression. There are certainly many efficient cathartics which are less dangerous.

CANCER OF THE CERVIX AND ITS TREATMENT

REPORT OF CASE

ROBERT M. LEWIS, M.D.

BALTIMORE

If all cases of uterine cancer could be seen in their incipience, and appropriate treatment given, the end-results would be brilliant. I herewith summarize the history of a case of cancer of the cervix which is interesting because it is the earliest case of the kind that I have seen.

REPORT OF CASE

History.—J. A. E. M., woman, aged 48, married, primipara, referred, June 15, 1916, by her family physician, Dr. Roland Fisher, Denton, Md., complained of uterine hemorrhage. A working diagnosis of very early operable cancer of the cervix was made. The final diagnosis was squamous cell carcinoma of the cervix. The patient had suffered with a constant bleeding from the uterus for the last one and one-half years. Her clothes were saturated with blood, requiring frequent changing every day. She was unable to tell whether she had menstrual periods or not, as the flow of blood was so continuous and free. Some loss of strength was also noted.

Examination.—There was no loss of weight and no pain or discomfort anywhere. There were no local symptoms referable to the bladder or rectum and no indigestion or cough. The general physical, as well as the other routine examinations, revealed nothing to contraindicate operation. The abdominal examination was entirely negative. No glands were palpable in the inguinal regions. Pelvic examination revealed a moderately relaxed outlet. The cervix was small and firm; from the external os a small bud of bleeding granular tissue protruded. This was removed with forceps for microscopic examination. (A frozen section cut within a few minutes of its removal showed that this was squamous cell carcinoma.) The body of the uterus was in good position, normal in size and shape, and freely movable. The ovaries were normal. The broad ligaments were not infiltrated.

Operation and Results.—I performed an abdominal panhysterectomy, June 17, 1916, the parametrium and paracervical tissues being removed widely. No enlarged glands were found. Convalescence was uneventful as one would expect, and the patient has remained well to this day.

COMMENT

The area of disease was tiny. The growth had become pedunculate, and most of it was removed by the original curettage. The disease found in and beneath the cervical mucous membrane measured about 1 cm. across. Further sections of the rest of the cervix revealed no other involvement. No disease was found in the parametrium.

Proverbially, "hindsight is clearer than foresight." Of course, if one could be sure in such a case that the size of the surface growth represented the extent of the disease, and that the latter did not burrow back widely into the cervical tissue, an amputation of the cervix, or even in this exceptional instance, a local cauterization, would be quite sufficient to effect a cure.

Unfortunately, until one has an extirpated specimen in one's hand, and, indeed, even then, one cannot tell how far a cancer may extend into the neighboring and apparently healthy parts.

I have often recalled a regrettable instance in which I amputated a cervix that appeared to be hypertrophied, but not the seat of a carcinoma. Examination of the specimen after removal disclosed an early squamous cell cancer well up in the cervical canal and apparently removed in toto. In spite of the fact that

the amputation seemed well wide of the disease, I urged the patient to submit to a radical panhysterectomy. She refused to consider it, and later died of cancer.

Another typical instance was that of a patient examined by a well-known gynecologist in whom the disease appeared in a plaque just above the os, measuring only 1 or 2 cm. across its surface. The cervix was not enlarged. Curetting, however, proved that it was entirely honeycombed with carcinoma.

Occasionally, a radical hysterectomy is not possible on account of the general condition of the patient. In such a case (as yet unreported) the patient was operated on by Dr. P. McC. Keating, in 1914. After performing a high cervical amputation, Dr. Keating discovered a very early cervical cancer. Nothing further was done, since to subject the woman to a radical operation would have been to court disaster, and no radium was available. It is gratifying to find that now, nearly five years after operation, the patient remains well—a living evidence of the surgeon's good judgment.

THE IDEAL TREATMENT

What now constitutes the ideal treatment of this type of case? We all remember the old rule of table-manners to the effect that "all things that can be eaten with a fork must be eaten with a fork." Ten years ago this might have been parodied to read: "All patients with cervical cancer that can be operated on, must be operated on."

During the last few years there has been a great increase in experience in the use of radium, which has established it in all cases as a formidable rival of the accepted Wertheim operation. The high mortality of the latter—even in most skilful hands—as well as its failure to effect a permanent cure in the great majority of the extensive, though still possibly operable, cases of cervical cancer have almost or quite persuaded many that it should be given up, and treatment with radium substituted.

Kelly, Burnam, John Clark, Ransohoff and others believe that a very high percentage of early cervical carcinomas can frequently and quickly be destroyed with radium alone. This is quite certainly true. My own opinion is that in this kind of case there is an excellent chance of cure either by the use of radium or by an operation well performed, but that the best chance is given by first treating the condition in the early cases thoroughly with radium, and then performing the usual wide abdominal panhysterectomy.

I do not believe that the results will be so good if the procedure is reversed, i. e., if the operation precedes the use of the radium. Before operation we are able to place the radium high up in the cervix close to the parametrium, while after it the vagina is shortened and the radium cannot safely be placed near the area of danger. In the case of early cervical cancer, operation should be comparatively easy and the mortality correspondingly low.

Given an operable but extensive cancer of the cervix, I believe our best chance of cure lies in the use of radium alone. Even if the mass shrinks to small proportions after radiation, the safest course is not to operate but to depend on further heavy treatments with radium.

Finally, when confronted with an inoperable cervical cancer, I do not believe that the use of any of the

palliative measures, such as slow heat or acetone, are to be considered, as the results of none of them are even comparable with those obtained by the intelligent use of a sufficient quantity of radium. By it the great majority of patients in whom the disease is distressingly extensive can be tremendously improved, and some even cured.

Clinical Notes, Suggestions, and New Instruments

A CASE OF COMPLETE VOLVULUS OF THE ENTIRE MESENTERY

WALTER D. WISE, M.D., BALTIMORE

REPORT OF CASE

Mrs. X, admitted to the hospital, Oct. 31, 1919, had been operated on two years previously in another city for pelvic trouble, but had not entirely recovered, having some abdominal discomfort and, at various times, attacks of severe pain and vomiting. On the day before admission she was seized with an attack more severe than usual and grew progressively worse, vomiting was constant, the pain was severe, and constipation was complete. She was operated on in about thirty hours after the beginning of this attack. An incision to the left of the previous scar gave entrance into the free abdomen and showed considerable straw-colored fluid and a loop of distended intestine. Under the scar was an intestinal coil tightly adherent to the parietal wall and containing in its wall a rather firm mass; running from this mass there were two bands, one of which was causing the obstruction. Both were released, and the distended and discolored loop began immediately to improve in appearance. The adherent section of the bowel was easily freed, and could then be brought up into the field. It was seen that a mass about the size of an egg was embedded partly in the intestinal wall and slightly in the mesentery. By tedious dissection it could be removed in its capsule without irreparable damage to the intestinal wall. The peritoneal coat of the intestine was sutured satisfactorily and the abdomen closed. During the dissection the diagnosis of the tumor had been suspected, and a section revealed that the suspicion was correct: it was a gauze sponge. Convalescence was smooth and satisfactory for seven days, when there was an attack of pain and some vomiting, which were relieved by an enema. Three days later, the patient had a similar but more violent attack beginning in the late afternoon. I did not see her until the next morning. She had been vomiting persistently and was considerably shocked or prostrated. Pain was of moderate degree, and the bowels had moved in the early morning as a result of an enema. Because of the character of the vomiting and her general appearance, an immediate operation was advised. Exploration revealed adhesions of the intestine to the parietal wall and almost countless numbers of viscerovisceral adhesions. The small intestine was moderately distended and very dark in color. On separation of any of the adhesions, there was profuse venous bleeding. Even with the most careful handling and gentleness, hemorrhage soon became a factor to be considered. It seemed impossible to locate the cause of the obstruction. However, by patient dissection, with considerable loss of blood, a view was finally obtained. It could be made out that there was a herniation of a large section of intestine through an arch made by two adherent loops, but reduction of this did not change the appearance of the bowel. It was then seen and could be demonstrated to onlooking surgeons that there was a torsion of the mesentery of at least one complete turn, probably a turn and a quarter from right to left. The adhesions were by this time freed sufficiently to permit of rotation of the mesentery, and as soon as this was done the intestine resumed its normal color. There were a considerable number of thrombosed vessels in the mesentery, but

as the subsequent history disclosed, not enough to cause trouble. As soon as the torsion was relieved, the venous bleeding ceased. The abdomen was closed except for a small drain. Salt solution was given during the operation and subsequently. The patient had a surprisingly calm convalescence, and left the hospital, December 6, restored to health.

COMMENT

Torsion of the entire mesentery is a rare condition. In 1903, Dr. George Tully Vaughan¹ reported a case of his own seen at postmortem, and reviews the literature, abstracting the histories of twenty other cases; of these, seventeen came to operation, with four recoveries—a mortality of 76 per cent.

In 1914, Weible² reported a case in which the patient recovered, and gives a summary of sixty-six other cases, including those reported by Vaughan; of these there were twenty-two recoveries.

In 1917, Vaughan³ reported another case of twisting of the whole mesentery, with a loss of the patient on the table.

In 1917, Garrow⁴ reported a case seen at necropsy in which there was a twist of three and one-half turns, or 1,260 degrees.

According to these figures, the case herewith presented is the seventieth to be reported, and the twenty-third in which the patient recovered.

1800 North Charles Street.

QUININ IN INFLUENZAL PNEUMONIA

A. J. CAFFEY, M.D., MILWAUKEE

During the epidemic that began in the fall of 1918, I used quinin sulphate in influenza and influenzal pneumonia chiefly for its diaphoretic and antifebrile effect. From a clinical study at that time, I found that patients could take liberal sized doses of from 10 to 20 grains every four hours the first day, and 5 grains every four hours during the course of the disease, without showing marked signs of cinchonism.

Since reading Cohen's¹ article on the treatment of the pneumonias, I have been using quinin hydrobromid, as I found it difficult to get the dihydrobromid, which he recommended as the preferable salt; however, from a study of the effect of this salt, the hydrobromid, it seems to have given more satisfaction than the sulphate, in that the patients seemed more restful, it reduces the fever promptly, and in most instances keeps it under 100 F.; and in hospital cases in which blood counts were repeatedly made, I found usually following the first large dose a marked leukocytosis; I never found a real crisis in any of the cases in which it was used. This may not be due entirely to the effect of the drug, because, most of the influenzal pneumonias being bronchial and lobular in type, the course is by lysis rather than by crisis, which occurs usually in the lobar type.

I gave 25 grains for the first dose, 10 grains for the second dose, and continued throughout the course of the disease with 5 grains every four hours; and from my limited study of its effect, I agree with Dr. Cohen that the quinin salts combat bacterial poisons and tissue poisons, and give clinical evidence that they are pneumococcidal if given in sufficient doses. I have never had a complaint of quinin amblyopia or marked tinnitus aurium and head noises which patients usually complain of when the drug is used in other troubles. Since quinin is said to be echolic, I do not know what effect it might have in pregnancy accompanying pneumonia, as none of my patients were pregnant during their illness.

I have never felt that the emergency of the effect of quinin in any of my cases justified the method of administering it intravenously or intramuscularly. It seems to me that the disturbance and pain incident to this method of administration would have a bad effect on any one ill with pneumonia, and there is always a possibility of abscess formation with necrosis when a large dose is given intramuscularly.

COMMENT

This treatment, quinin being the chief drug used in combating the disease, with other auxiliary drugs, such as digitalis, atropin and pituitary extract, good nursing, nourishing diet, fresh air, etc., was followed out in twenty-seven cases of influenzal pneumonia with only one death. It is understood, of course, that the number is too small to establish the specificity of quinin. The low mortality in my series may have been accidental, but it is the lowest I have ever had in the same number of cases in other years.

ICE-BOX FIXATION IN THE WASSERMANN TEST FOR OFFICE PRACTICE

OSCAR BERGHAUSEN, B.A., M.D., CINCINNATI

A year ago I¹ advocated the method of ice-box fixation in the Wassermann test, using simple alcoholic extract of syphilitic organs as antigens. Further experience has convinced me that this method is satisfactory in the examination of a large number of serums for diagnostic purposes. The results obtained are usually either strongly positive or negative when the fixation is carried out at a temperature not exceeding 4 C (39.2 F.). Slight inhibition in hemolysis is unusual and, when obtained, is always recorded as negative. Serums obtained from patients not syphilitic always give a negative reaction.

When cholesterinized antigen is used in the original Wassermann reaction with fixation in the water bath at 37 C. (98.6 F.), more positive reactions are obtained than with simple alcoholic extracts as antigen and fixation in the ice box over night; but serums obtained from patients definitely not syphilitic may give a positive reaction with cholesterinized antigen, and for this reason the result is not always reliable for diagnosis. When the serum has been obtained from a syphilitic patient under treatment, some attention may be paid to a positive result obtained only with cholesterinized antigen, since this reaction is the last to disappear.

After examining about 3,000 serums at the Cincinnati General Hospital, which has a modern refrigerating system, the problem arose as to how it might be possible to secure a constant low temperature of 4 C. or less by a simpler method, in order to make the method of ice-box fixation practical for a smaller laboratory. After a little experimentation I found that the "Frigidaire" refrigerator, manufactured in Detroit, was satisfactory for this purpose. It is run by electricity at an expense of less than \$5 a month, and can be set to maintain a constant temperature of 4 C. in the lower chamber. It has been my custom to place the rack containing the test tubes in the lower left hand chamber, cover them with a sterile towel, and remove them about sixteen hours later, finishing the reactions by adding the requisite amount of sheep corpuscles and amboceptor and then placing the racks in a water bath at 37 C. Occasionally, serums which have anticomplementary properties, especially when they have been preserved for three or four days, will show a lack of hemolysis in the control tube containing no antigen. Such serums must be tested again, the standard Wassermann technic of fixation in the water bath at 37 C. for one hour being used. Usually it will be found that such serums give a strongly positive reaction by this method.

As a routine, two alcoholic extracts of syphilitic organs are used as antigens. It is not necessary to employ the Noguchi acetone insoluble fraction of lipoids as antigen, for simple alcoholic extracts give better results when the method of ice-box fixation is used. Comparative results, with the same antigen and the same serums, have shown this method to be more satisfactory than the Hecht method, with active serum. The reactions are always either distinctly negative or positive; slight inhibition in hemolysis occurs infrequently. Results are thus recorded: Wassermann (original) negative or positive; Wassermann (Frigidaire) negative or positive.

CIRCUMCISION FORCEPS

MYER N. MOSKOVICH, M.D., PHILADELPHIA

The circumcision forceps here illustrated consist of a pair of handles, not unlike those of the ordinary hemostatic forceps, terminating in circular jaws corrugated on their inner surfaces and having seven equidistantly placed indentations to permit the passage of sutures while the forceps are still in place. Various sizes may be had, and they are best employed in older children and in adults when no edema or swelling of the prepuce exists.

The forceps may be used with any of the various methods of performing a circumcision. The blades are opened and one ring is passed over the penis with the handles pointing toward the head of the patient. A dorsal slit is now made and the ring brought up to the level of this slit, with the handles between the cut edges of the prepuce. The latter is everted over the ring, the second ring passed over the head of the penis and the forceps clamped. The projecting prepuce is cut with a knife or curved scissors, sutures are inserted at the points of indentation, and the forceps are removed.

Circumcision forceps.

It will be difficult to convince the reader of the full value of this little instrument, because of the fact that the doing of a circumcision is already such a simple procedure that further simplification hardly seems possible. Certain facts, however, remain:

1. The time taken to perform the operation is diminished considerably.
2. Perfect coaptation with earlier union and a minimum amount of scarring results.
3. The procedure is practically bloodless, all bleeding points being checked, through mere pressure, before the forceps are removed.

Jefferson Medical College.

A NEW USE FOR COVER GLASS FORCEPS

RALPH WALDO PLACE, M.D., SOMERVILLE, MASS.

Cilia forceps are not what they ought to be. I have tried several and I have bent and filed them; but they will not hold the slippery hairs in trichiasis. Some time ago I gave them up in favor of ordinary spring forceps, the kind opticians use in setting up eyeglass frames and known as tweezers. These served me well, and I still use them sometimes in the "corners"; but one day after working a long time on a particularly difficult case I happened to try a pair of cover glass forceps. These grasped the hairs better than anything I had ever tried, and I have used them satisfactorily ever since. Of course, they should be used only for this work, and they should be carefully sterilized.

165 Medford Street.

A Case of Quadruplets.—I recently delivered a woman, after a six months' pregnancy, of quadruplets. A reference to statistics shows that they occur once in every 371,126 deliveries, and for this reason I thought it worth while to publish my experience. This was a case of multiple impregnation of a single ovum, as there was a common chorion. Each fetus was within its own amniotic sac, and all were males. The placenta, if not a common one, was so anastomosed that it could not be differentiated. All the fetuses were dead at the time of delivery.—CHARLES E. FALLET, M.D., De Soto, Mo.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

LACTIC ACID-PRODUCING ORGANISMS AND PREPARATIONS (See New and Nonofficial Remedies, 1920, p. 156).

BACILLUS BULGARICUS-SQUIBB.—A pure culture in vials, of the *Bacillus bulgaricus* type A, the *Bacillus bulgaricus* type B (*Bacillus acidophilus*) and *Bacillus paralacticus*, each vial containing 12 Cc.

Actions and Uses.—*Bacillus Bulgaricus-Squibb* is designed for internal administration, topical applications in nasal and throat affections and for direct application to abscesses, wounds and old ulcers. See general article, Lactic Acid-Producing Organisms and Preparations, New and Nonofficial Remedies, 1920, p. 156.

Dosage.—The contents of one tube daily after meals or before retiring. The culture is marketed in packages of twelve vials. The culture should be kept in a cold place, and is not guaranteed beyond the date stamped on the package.

Manufactured by E. R. Squibb & Sons, New York. No U. S. patent or trademark.

POLLEN EXTRACT PREPARATIONS (See New and Nonofficial Remedies, 1920, p. 226).

POLLEN ANTIGEN-LEDERLE (SPRING TYPE).—A liquid obtained by extracting equal parts by weight of dried pollens of timothy, red top, June grass, orchard grass, sweet vernal grass, meadow foxtail, meadow fescue, rye and wheat by a vehicle of 67 per cent. glycerine and 33 per cent. saturated solution of sodium chloride. It is standardized so that each Cc. contains 14,000 pollen units; a pollen unit has been arbitrarily chosen by Kocssler, Noon and Freeman as the equivalent of one-millionth gram (0.000001 Gm. or 0.001 Mg.) of pollen. The Hygienic Laboratory has prescribed no U. S. Standard of Potency. The antigen after preparation is made into fifteen different dilutions by the addition of a proper amount of the glycerine-sodium chloride solution diluent.

Actions and Uses.—See general article, Pollen Extract Preparations, New and Nonofficial Remedies, 1920, p. 226.

Dosage.—The product is supplied in fifteen different doses. Each dose consists of 0.1 Cc. of the respective dilution. Accompanying each dose is a vial containing 9 Cc. of sterile water with which to make the pollen antigen of isotonic strength immediately before administration. For prophylaxis, the complete series (doses 1 to 15) containing progressive amounts of pollen protein should be given, beginning about six weeks before the hay-fever season. For treatment of an actual attack of hay-fever, fewer doses are generally sufficient.

Manufactured by the Lederle Antitoxin Laboratories, New York. No U. S. patent or trademark.

Pollen Antigen-Lederle (Spring Type) Series A.—Marketed in packages of five vials containing for each consecutive dose (numbers 1 to 5 inclusive) 2.5, 5, 10, 20 and 25 pollen units, respectively, and five vials of sterile water with which to make the proper dilution of each dose.

Pollen Antigen-Lederle (Spring Type) Series B.—Marketed in packages of five vials containing for each consecutive dose (numbers 6 to 10 inclusive) 30, 50, 75, 100 and 150 pollen units, respectively, and five vials of sterile water with which to make the proper dilution of each dose.

Pollen Antigen-Lederle (Spring Type) Series C.—Marketed in packages of five vials containing for each consecutive dose (numbers 11 to 15 inclusive) 250, 375, 500, 750 and 1,000 pollen units, respectively, and five vials of sterile water with which to make the proper dilution of each dose.

Pollen Antigen-Lederle (Spring Type) Complete Series.—Marketed in packages containing 15 doses as described in Series A, B and C above.

Pollen Antigen Immunity Test—Diagnostic Test for Spring Type Hay-Fever-Lederle.—Consists of 0.01 Cc. of No. 15 dilution of pollen antigen-Lederle (spring type). It represents 100 pollen units of the combined pollen protein. May be used cutaneously or intradermally.

SATURDAY, APRIL 24, 1920

The postal situation is well known by all our readers. Matter sent by parcels post, and periodicals, have been meeting with lengthening delays in transmission. More recently delivery of even first-class mail has been delayed. This item is published to explain delay which may occur in the receipt of THE JOURNAL. The copies are delivered at the Post Office at the usual time each week, and any delay in their receipt must be charged to the postal conditions. It is hoped that our readers will allow for the present difficulty and not request additional copies until sufficient time has elapsed to make sure that missing copies will not be received.

EXPERIMENTAL LOBAR PNEUMONIA

Many attempts have been made to produce lobar pneumonia experimentally in animals, but only with occasional and partial success, and under experimental conditions not encountered in the spontaneous disease in man. In order that experimental results may be of the maximum value, a method is required by which lobar pneumonia can be regularly produced in animals, without otherwise modifying their physical condition or surroundings, so that the clinical, bacteriologic and pathologic changes of all stages of the disease may be studied and compared with the disease in man. The work of Blake and Cecil¹ at the Army Medical School, on the experimental production of lobar pneumonia in monkeys by the intratracheal injection of pneumococci, appears to fulfil these requirements, and furnishes an enlightening chapter in experimental medicine.

In a series of thirty-seven normal monkeys, lobar pneumonia was produced in thirty-two; two others died of pneumococcus septicemia; and in three which received small doses, no disease was produced. Pneumococci, in amount from 1 to 0.000001 c.c. of an eighteen hour culture, were introduced into the lumen of the trachea by means of a sterile needle inserted between the cartilages below the larynx. In most of the animals Type I pneumococcus was used, but pneumonia was also produced by Types II, III and IV.

Following the inoculation, blood cultures, leukocyte counts and observations of the temperature, clinical course and physical signs were made. Symptoms of illness usually appeared in from twelve to thirty-six hours after inoculation. The report is accompanied by protocols of a number of the cases. The temperature curves, often with critical drops on the seventh to the ninth day, were similar to those seen in lobar pneumonia in man. Blood cultures showed varying grades of pneumococcemia, which in nonfatal cases usually disappeared before the crisis, but in some of the severer infections increased enormously before death.

In several respects the features of experimental lobar pneumonia in monkeys showed a parallelism with those of the disease in man which is not only of great experimental interest, but opens the way for the determination of a number of clinical questions related to lobar pneumonia, the answers to which till now have been impossible or largely matters of opinion or surmise.

The finding of pneumococci in the blood within six hours after the introduction of the organisms into the trachea, and before the signs of pneumonia appeared, will go far toward clarifying our conception of the mode of invasion in pneumonia, whether hematogenous or bronchigenic, and furnishes apparently clear evidence in favor of the bronchigenic origin of the disease. This view is further strengthened by the failure of intravenous or subcutaneous injections of pneumococci to produce pneumonia, and by the observation that even when the intratracheal route was employed in monkeys, with lobar pneumonia usually resulting, there were occasional instances in which a pneumococcus sepsis was produced without clinical or post-mortem evidence of lobar pneumonia.

By examining the animals early (three hours) after intratracheal inoculation, Blake and Cecil were able to demonstrate the penetration by pneumococci of the bronchial wall near the hilum. The further spread of pneumococci, as observed in other animals in the series, was apparently by way of the interstitial tissue and lymphatic system of the lung, and hepatization began centrally and proceeded toward the periphery of the lung. The pathology of the pneumonic lesion produced in the monkey was identical with that seen in lobar pneumonia in man.

The preliminary rise in leukocytes in monkeys after inoculation was followed by a fall, the rapidity and extent of which was proportional to the severity of the disease and the degree of pneumococcal invasion of the blood. In the less severe cases, the preliminary fall in leukocytes was followed by a rise, accompanied by decrease in the number of pneumococci in the blood, until the blood became sterile, usually several days before crisis. This relation of leukocytosis to severity of disease, in which failure of leukocytosis was indicative of serious prognosis, affords experimental sup-

1. Blake, F. G., and Cecil, R. L.: J. Exper. Med. 31: 403 (April) 1920.

port of the clinical observation in man that, in general, the prognosis in patients showing a moderate leukocytosis is better than in those in whom there is no leukocytosis or a leukopenia.

Instances of empyema, delayed resolution, pericarditis and persistent pneumococcal sepsis occurred in monkeys just as in the natural disease in man. Monkeys inoculated in the throat and nose with pneumococci did not develop lobar pneumonia, although the organisms persisted for many days, whereas inoculation of the lower respiratory tract regularly produced the disease. As the authors point out, these facts indicate that in monkeys, something besides the mere presence of virulent pneumococci in the upper respiratory tract is necessary for the development of pneumonia; and presumably the same is true in man. The rôle of contact with the sick was shown in one experiment, in which one animal of several exposed to monkeys sick with pneumonia developed lobar pneumonia.

In addition to the elucidation of the mechanism of infection in pneumonia, this demonstration of a method whereby lobar pneumonia may be produced regularly under controllable experimental conditions is perhaps of still greater importance in that it affords opportunity for the experimental study of prophylactic immunization against pneumonia, and for determining the actual value of antipneumococcal serums in the cure of the developed disease. We shall await the results of these investigations with interest.

SCURVY NOT A BACTERIAL DISEASE

Acquired beliefs are not easily given up when once they have become deeply rooted in the customary thought and writing of a period. This fact has often been illustrated by the tenacity with which medical men tend to cling to traditional theories that have been tried by the tests of science and found wanting. It was a long time before the version of the etiology of malaria now current became accepted by every physician. Before the possible significance of insects in the transmission of disease became common knowledge, the idea of ascribing real bodily danger rather than mere temporary discomfort to the seemingly unimportant mosquito made slow headway.

On the other hand, when once some novel type of agent has been clearly demonstrated to be concerned in the causation of hitherto unexplained diseases, it soon tends to achieve a degree of popularity that may subsequently actually become detrimental. Thus, when bacteria were at last universally admitted to be potent causes of pathologic changes in man, bacteriology was promptly called on to explain many of the unsolved mysteries of disease. For centuries, scurvy was regarded as a disease due to dietetic errors. Then came the time when the theories of the etiology of scurvy began to include that of a bacterial origin. Fol-

lowing Coplans,¹ Jackson² and her collaborators in this country have offered some experimental support for this view. Thus they found coccus-like bodies in microscopic sections of lesions in scorbutic guinea-pigs, and they isolated gram-positive and gram-negative organisms from the diseased joints, muscles and lymph nodes of these animals. Pure strains of these bacteria introduced into guinea-pigs gave rise in most instances to hemorrhagic and other lesions in the bones, joints, muscles, lymph nodes and organs.

It is not difficult to believe, however, that animals in a scorbutic condition due to dietary deficiencies may readily be susceptible to a secondary bacterial invasion, just as terminal infections in many chronic conditions have no direct relation to the primary disease. Of late the study of experimental scurvy has been extensively prosecuted in England and America, with the result that the disease can now be evoked, averted or cured with considerable precision by purely dietary control. This fact of itself negatives the probability that bacterial infection is a prime factor in the genesis of scurvy. The products of putrefaction have also been charged with responsibility for the appearance of scurvy. Torrey and Hess³ have concluded, however, that scurvy, both of guinea-pigs and of infants, is not associated with an overgrowth of putrefactive bacteria in the intestinal tract.

The most convincing evidence against the bacteriologic hypothesis has been offered by Givens and Hoffmann⁴ from the Research Laboratories of the Western Pennsylvania Hospital, Pittsburgh, who have made bacteriologic examinations of the blood and tissues of scorbutic animals. Blood from the latter, regardless of the diet producing the disease, has been found to be sterile. The enlarged front joints of guinea-pigs developing scurvy on oats alone were sterile; this was likewise true in the majority of cases of guinea-pigs developing scurvy on other special diets. Occasionally, staphylococci or diplococci were isolated; but these could not be made to produce scurvy when introduced into healthy guinea-pigs. The intestinal flora likewise showed no differences between the scorbutic and non-scorbutic animals which could explain the genesis of the disease.

With the bacteriologic hypothesis left without tenable scientific confirmation, with McCollum's theory that chronic constipation is a decisive factor abandoned,⁵ and with an abundance of experimental evidence in favor of the view that dietary deficiencies play the decisive part in the genesis of scurvy, the current

studies on antiscorbutics are placed on a more stable foundation. It matters little that they have in the main been tested primarily on animals, notably the guinea-pig and the monkey; for the essential identity of the disease in these animals and in man has been generally accepted by investigators.

MEDICAL ASPECTS OF THE JUVENILE COURT

The first juvenile court in the United States, as we are informed by Belden,¹ was established by the Illinois legislature, July 1, 1899. It marked the beginning of the juvenile court movement in this country. Previous to that time some states had provided for separate hearing of children's cases, but the Illinois law was the first serious attempt in the United States at modification of court procedure so far as it related to children. Shortly afterward, Colorado came to the front and passed a special juvenile court law, which has been a model for other states.

In general, the special modification of court methods which has been necessary in the development of the juvenile court has been based on the fundamental principle that the child is a ward of the court. One of the chief distinctions between the usual criminal procedure and the juvenile court procedure lies in the matter of evidence. The purpose of the court is not to discover whether a crime has been committed but rather to ascertain what were the underlying conditions that caused the commission of the crime. Were they physical, mental, social? Then comes the question as to what should be done with the culprit for the best interest of the people and of the child.

Obviously, the matter of first importance is the physical and mental status of the child, for these are intimately associated with what he is and how he became what he is. Furthermore, a knowledge of his family and personal history is equally essential to a successful rehabilitation. Such investigation requires special adaptability on the part of the court. The procedure may be regarded as extralegal. The problems presented require expert and special knowledge not usually available. To Illinois belongs the credit for introducing such practical study of children before the courts, by the establishment of the Juvenile Psychopathic Institute. Shortly afterward the Seattle juvenile court established a "department of social diagnosis," which is still maintained. Strangely enough, physical examinations are given much more generally than mental examinations. In thirteen courts, mental clinics are maintained as part of the court organization. An excellent plan is that of the Judge Baker foundation of Boston, which provides that a large proportion of children before the juvenile court are given thorough

physical examinations; their mental condition is thoroughly studied, and especially qualified investigators attached to the staff gather social data. All the information in a given case is then assembled and studied at a staff conference, and the diagnosis of the child's condition, and a recommendation as to the kind of treatment needed, is made by the director or his assistant. The group clinic idea is thus utilized to its utmost in proper placing of the child who may be either physically, mentally or morally deficient.

As a result of this work, some of the underlying causes of child delinquency and neglect are becoming more evident. The need for early recognition and treatment of abnormalities in physical, mental or moral development has been conclusively demonstrated. In a statistical table, Belden shows that there are now 246 courts, representing practically every state in the Union, which give some special attention to these problems. In fourteen states there was no report of mental examinations in clinics or by persons having special psychiatric knowledge. There remains, then, considerable need for improvement and for the establishment of uniform methods of study. The problem is a fundamental one for the community, and physicians may well lend their aid to its solution.

BEANS AND GROWTH

The modern chemistry of the proteins has profoundly modified some of the older tenets of nutrition. With the advent of a better knowledge of the digestion and disintegration of the proteins into amino-acids, and with an appreciation of the part which the latter play as the real nitrogenous nutritive units for the construction of protein in the body, new points of view have arisen. In constructive metabolism, at least, the physiologist must deal primarily with amino-acids, of which familiar proteins are known to furnish a varied assortment. Some of these are not essential in the sense that they must be furnished as such to the organism; for they can be synthesized by the living tissues. Other amino-acids, on the other hand, and perhaps a majority of those related to proteins, cannot be thus built up anew by animal structures; hence, so far as they may be indispensable, they must become available to the body in the food if the organism is not to suffer from a lack of such "building stones," as they have been called.

Information of the sort just referred to has served to explain why gelatin, for example, is not a "complete" protein from the nutritive standpoint, and why it cannot serve as the sole source of nitrogenous units in the body. Gelatin lacks in its chemical makeup certain of the amino-acids, without which protein cannot be built up in the body. Thus it lacks cystin, tryptophan and tyrosin. Other isolated proteins are known to be chemically defective in comparable ways.

In some instances it is a relative rather than an absolute shortage of some amino-acid component that limits

1. Belden, Evelyn: Courts in the United States, Hearing Children's Cases, Pub. 65, Children's Bureau, U. S. Department of Labor, Government Printing Office, Washington, D. C., 1920.

the nutritive value of a protein. Osborne and Mendel,¹ for example, have furnished striking instances of the significance of this in actual nutrition experiments. One of the most impressive cases has just been elucidated by Johns and Finks² at the Protein Investigation Laboratory of the Bureau of Chemistry in Washington. The principal protein of the navy bean has been shown to be inadequate for growth even when an abundance of other needed foodstuffs is supplied in the ration. An explanation had been sought in the ready putrefaction of the beans, leading to supposedly harmful products in the intestine and thereby retarding growth. But Johns and Finks have ascertained that the protein of the bean is exceptionally deficient in its yield of the amino-acid cystin, an essential source of sulphur for the body tissues. When cystin or a cystin-yielding protein is added to the bean diet, growth at once becomes satisfactory, provided the beans are cooked. Why cooking is a significant factor in making the bean diets more ideal is not clear, unless the process renders the protein more readily digestible.

Under ordinary circumstances, of course, navy beans do not represent the sole source of protein, even to ardent "bean lovers"; they are supplemented by other protein foods. Nowadays, however, it occasionally happens that diets are extremely limited by intentional or accidental circumstances. Knowing the limitations of the navy bean, we can avert nutritive disaster, if it should be threatened through exigencies of the ration, by making good what the delectable legume lacks.

Current Comment

LOOK UP ITS RATING

Modern business has become so complex that it is no longer possible for those engaged in trade to know, offhand, the financial responsibility of their prospective customers. The commercial agency is a natural development; it aims to supply the technical (financial) information which the conservative business man needs but is otherwise unable to get. When John Doe & Co. contemplates entering into business arrangements with Henry Roe & Son to a degree that involves financial obligations, it looks up Roe in the rating book of Dun or Bradstreet and probably calls for a special commercial report on the concern. These facts are so elemental and obvious as to be trite. The complexity of modern medicine, especially in the pharmacologic field, has made it a physical impossibility for physicians to know the scientific status of scores of pharmaceutical products put out under proprietary or brand names. It was recognition of this fact that brought about the creation by the American Medical Association of the Council on Pharmacy and Chem-

istry. This body of experts, serving without remuneration and reporting without fear or favor on the newcomers to the pharmaceutical world, places at the disposal of physicians unbiased information, free alike from prejudice or prepossession. As the commercial agency reports on the commercial probity of individuals and firms, so the Council on Pharmacy and Chemistry reports on what might be called the scientific probity of proprietary and unofficial pharmaceutical products. The commercial agency issues, at no small expense to its customers, rating books; the Council on Pharmacy and Chemistry issues, at a nominal price, "New and Nonofficial Remedies." The commercial agency, for a substantial fee, will furnish reports on business concerns; the Council on Pharmacy and Chemistry¹ will, without any expense to the profession, furnish reports on proprietary products used for the relief or cure of human ailments. The careful business man avails himself of the services of the commercial agency; there are financial interests at stake. The conscientious physician will avail himself of the services of the Council; there are, it may well be, lives at stake.

LONGEVITY IN THE UNITED STATES

The expectation of life or, better, the average duration of life at various ages and in different racial groups, has been a common theme of statistical inquiry. Improved and more exact methods of calculation, together with the accumulation of additional data, are, however, continually stimulating fresh studies in this field. A recent article by Forsyth² on the trend of longevity in the United States, although it deals only with the census records from 1890 to 1910, contains some important figures. In 1890 the expectation of life for a male native white of native parentage at 10 years of age was 56.1; by 1910 this had fallen to 54.1. At the age of 40 the expectation in 1890 was 32.8; in 1910, 29.9. In fact, in each age group and in both sexes the average expectation showed a notable loss for the two decades from 1890 to 1910. A large loss in expectation was also shown by the native white of foreign or mixed parentage. On the other hand, the foreign-born whites, especially the males, gained materially in the average duration of life during the same period. Forsyth emphasizes especially two points: first, the remarkable longevity enjoyed by native Americans of native parentage, which he considers probably unequaled anywhere else on earth; and second, the gradual loss of this superiority at a rate of about one year each decade. He seems inclined to attribute this "momentous retrogression" to certain unspecified "factors in the American mode of living"; but it seems evident that the conditions are very complex. The "native whites of native parentage" are being added to all the time from various racial stocks not perhaps as resistant as the original native stock. From decade to decade, therefore, the native whites of native parentage represent an ethnically different

group. Whether the loss in expectation is due to some mingling of less resistant strains or whether the shortening in average duration of life is due to purely environmental factors can perhaps hardly be determined. The question is one that must be considered in connection with the fact that in recent years in this country the general mortality has increased disproportionately in the ages above 40. At all events, the bearing of the census of 1920 on the trend of longevity will be awaited with interest.

ENCEPHALITIS IN HORSES

There occurs an epidemic disease of horses, known as enzootic encephalitis, or Borna disease, which has been observed in many parts of the world, including the United States. This disease exhibits certain resemblances to lethargic encephalitis, which makes it of peculiar interest at the present time. Not only are the symptoms in some respects similar to those of the human disease, but also the pathologic anatomy, as described by Joest and Deegen,¹ is much the same as that of lethargic encephalitis. In both diseases there is an absence of recognizable anatomic changes outside the central nervous system, in which in each the conspicuous feature is a marked perivascular infiltration of small round cells, without polymorphonuclear infiltration or much involvement of the meninges. The vascular lesions are chiefly in the brain, the cord being much less involved. Numerous studies of the equine disease have left the etiology undetermined. While some have attributed it to an intoxication from infected food, several others have found cocci in the nervous tissues. A recent investigation of enzootic encephalitis in Argentina² has corroborated the previous anatomic studies and in addition has led to the isolation of a gram-negative diplococcus which produces what seems to be the same disease when injected subdurally into horses. In view of our complete lack of knowledge concerning the etiology of lethargic encephalitis, there is no little interest in this demonstration that a coccus, resembling somewhat the meningococcus, is capable of producing a marked nonsuppurative cerebral perivascular round cell infiltration, despite the fact that no such organism has been found in the human disease.

NEW ORLEANS SESSION

Sailing of S. S. Comas Cancelled

The Passenger Traffic Department, Southern Pacific Lines, advises that owing to labor disturbances at New York, it has been compelled to cancel the sailing of the S. S. *Comas*, which was scheduled to leave the port of New York, Wednesday, April 21, for New Orleans. Refunds may be secured on presentation of tickets at 165 Broadway, Room 2015, New York City, or if desired, the department will arrange for your trip to New Orleans by rail.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Beck in Los Angeles.—Dr. Emil G. Beck, Chicago, spoke before the Los Angeles Surgical Society, February 18, on "The Balance of Power in Immunity."

State Board Upheld.—A decision by the State Supreme Court of California has upheld the board of medical examiners in its action, two years ago, in suspending for one year the license of Dr. John K. Suckow, Los Angeles, on the ground that he had performed an illegal operation. The case was appealed to the higher court on the grounds that the board was not qualified to administer punishment and that the defendant had done nothing to merit suspension. Both of these claims were rejected.

State Society Meeting.—The annual meeting of the Medical Society of the State of California will be held at Santa Barbara, May 11, 12 and 13, under the presidency of Dr. Henry A. L. Ryfkogel, San Francisco, with headquarters at the Hotel Ambassador. Dr. Noble W. Jones, Portland, will discuss the "Prognosis After the Removal of Focal Infections;" Dr. Russell D. Carman of the Mayo Foundation, Rochester, will talk on the "Roentgenologic Aspect of Gastric and Duodenal Ulcers," and Edward C. Kendall, Ph.D., also of the Mayo Clinic, will speak on "A Chemical Consideration of the Thyroid."

Personal.—Dr. Wilfred H. Kellogg, Sacramento, who resigned as secretary of the state board of health last month, was appointed director of the state hygienic laboratory, Berkeley, April 3.—Dr. Robert K. Macklin, Pasadena, has just been discharged from the Letterman Hospital, San Francisco, after a long treatment for injuries received overseas. He was honored by fifty of his fellow practitioners from Los Angeles, March 28, who presented him with an automobile fully equipped.—Dr. Harry W. Martin, Los Angeles, sustained a fracture of the spine while diving into shallow water at the Bimini Baths near Los Angeles, April 19.

ILLINOIS

Chicago

Low Death Record for Chicago.—Health Commissioner Robertson announced on April 6 that the death rate for 1919 was 11.75 per thousand. The previous low record was 13.95 in 1904.

Crerar Library Closed.—The board of directors of the John Crerar Library announces that as it has been unable to secure an extension of its lease, the library will be closed May 1. It will be reopened as soon as the new building at the corner of Michigan Boulevard and Randolph Street is ready for occupancy. At present this is expected to be by September 1.

Illegal Practitioners Fined.—David Hertz of 2015 Potomac Avenue was arrested by the Department of Registration and Education of the State of Illinois, for practicing medicine without a license and was fined \$25 and costs.—Mrs. Katrina Smish of 4933 South Robey Street was also arrested by the department and fined \$25 and costs for practicing midwifery without a license.

Physicians Exonerated.—Dr. Ira R. Willets was exonerated by a coroner's jury, April 14, in the case of Blanche Warner who died April 1 at the German Deaconess Hospital from a supposed illegal operation.—A coroner's jury on April 16 recommended the release of Dr. William James Mitchell, held in custody in connection with the death of Mrs. Marie C. Hopkins. Dr. Mitchell was considered entirely free from blame.

Local Committee Organized for Relief of Vienna.—A Vienna Relief Committee has been organized to solicit funds for the relief of the starving inhabitants of Vienna, and an appeal has been issued through the secretary, Dr. Carl Beck. The circumstances of this once beautiful city are indeed pitiful. "She has become a dark and dreary place—the dreariest on earth. Resurrection seems hopeless," says a

letter from Dr. Adolf Lorenz and Prof. Anton Eiselsberg. The address of the relief committee is 1826 Conway Building.

MARYLAND

City to Open New Clinic.—The Baltimore City Health Department has recently opened a clinic at 2000 North Charles Street, especially for persons supposed to be suffering from tuberculosis. The municipal tuberculosis dispensary at 1418 Light Street, closed during the war, has been reopened by the health department. Commissioner C. Hampson Jones reports that the department now has four tuberculosis clinics in operation. The clinics are in charge of Dr. John E. O'Neill, physician in charge, Dr. Bartus T. Baggott, assistant physician, and Miss Anna L. Murphy, nurse.

Plans for Municipal Hospital.—Announcement has been made by Surgeon-General Ireland of the Army that the U. S. Army General Hospital No. 2, at Fort McHenry, will be given up by the Army June 1 and turned back to the War Department as "surplus property." In view of the fact, the mayor of Baltimore has named a committee composed of Dr. John M. T. Finney, chairman; Drs. Arthur M. Shipley, Winford H. Smith, Henry B. Thomas, C. Hampson Jones, and several prominent laymen, to inaugurate a movement to obtain the hospital buildings at the fort for a municipal hospital.

Measles On Increase.—Measles is claiming the attention of the Baltimore City Health Department; 216 new cases and two deaths having been reported during the past week. The situation is being watched closely because of the serious complications—frequently bronchopneumonia—that follow carelessness in handling cases of measles, which is approaching the epidemic stage in the city. Scarlet fever also appears to be on the increase, the new cases for the week numbering forty-eight. There were twenty-six cases of diphtheria and twenty-seven cases of chickenpox. Influenza lingers, the records of the department showing thirty-eight cases and four deaths.

County Districts Face Shortage of Physicians.—Unless steps are taken to offset the advantages offered by the large cities to young men entering the medical profession, the country districts will, in the near future, be without competent physicians, according to a statement recently made by Dr. John Whitridge Williams, dean of the Johns Hopkins Medical School. To meet the situation, he suggests the establishment by counties or by the state of public health centers, whose physicians and nurses would be paid regular salaries to supplement their incomes from regular practice. Some such arrangement as this will have to be made in the not distant future or the country districts will be without a sufficient quota of physicians.

Personal.—Dr. Adrian S. Taylor of the faculty of the Johns Hopkins University, and Drs. Ralph G. Mills and Charles W. Young, graduates of the Johns Hopkins Medical School, will leave June 5 to do medical work at University Hospital, Nanking, China. Dr. Thomas Dwight Sloan of the University Hospital, Nanking, recently addressed members of the Johns Hopkins Christian Association on "The Progress of Medicine in China."—Dr. John M. T. Finney will sail for London in June.—Drs. Harry W. Wheaton, Baltimore, and George F. Sargent, Towson, assistant physicians at the Sheppard and Enoch Pratt Hospital, Towson, have resigned.—Dr. Martin W. Peck, Towson, has been appointed assistant physician at the Sheppard and Enoch Pratt Hospital.—Dr. Elmer V. McCollum, Ph.D., has been made a corresponding member of the Royal Academy of Belgium.—At the recent commemoration day exercises of Johns Hopkins University, a portrait of Dr. John Whitridge Williams, dean of the medical school, was presented to the university by Dr. William H. Welch, and a portrait of Dr. Florence R. Sabin, professor of histology, was presented by Dr. William H. Howell.

MASSACHUSETTS

Personal.—Dr. Edward P. Hand, formerly city physician of Holyoke, has been elected physician to the Tuberculosis Hospital and has been succeeded by Robert E. Cleary.

Bill to Raise Standard Rejected.—By a vote of fifteen to seventy-one the house of representatives, March 31, refused to substitute for an adverse committee report the bill to raise the standard for the regulation of the registration of physicians.

Will Not Extend Vaccination Law.—By a vote of eight to seventeen, the state senate rejected the bill reported unanimously by the committee of public health to extend the provision of the compulsory vaccination law to pupils in private schools.

Report of the Cancer Commission of Harvard University.—The seventh annual report—1918-1919—of the Collis P. Huntington Memorial Hospital for Cancer Research states that the work of the institute during the two years included in the report was considerably curtailed, owing to the call of the war on the members of its staff. With the return of peace, reorganization of all research work has been going on. The facilities of the organization have been insufficient to accommodate the public, because of the interest being taken by the public and the medical profession in the treatment of cancer by radium. Special attention has also been given, during the past year, to the establishment of a new roentgen-ray machine of great power for use in the treatment of cancer. In the biologic department, studies are being made of changes in the living cell, which is an indispensable prelude to the study of the nature of cancer. A new building is proposed for the housing of the new roentgen-ray equipment. During the coming year the commission proposes to maintain its hospital for the investigation of the treatment of cancer and allied diseases and to make a special study of the use of radium and of the new roentgen-ray apparatus.

MICHIGAN

Personal.—Dr. Wynand Van K. Pyle, Grand Rapids, has returned after two years' service with the 339th Infantry in Russia.

Society Meeting.—The annual meeting of the Michigan State Medical Society will be held at Kalamazoo, May 25 to 27, under the presidency of Dr. Charles H. Baker, Bay City.

Tuberculosis Clinic.—A free clinic for tuberculosis is being conducted at Ludington under the auspices of the state anti-tuberculosis society and is under the charge of Dr. Edwin R. Van der Slice, Lansing.

District Versus Divisional Plan.—The Detroit Department of Health, in its *Weekly Review* of April 10, says that theoretically, if a nurse is confined to a district and performs all service—school, tuberculosis, contagion, infant welfare, and prenatal—within the district, more will be accomplished than if the same nurse confines herself to one service and covers a wider territory. During the three months' trial of the district plan in Detroit, the following figures show that more nursing service is actually being performed under the new system:

FIELD NURSING SERVICES PER NURSE PER MONTH	Divisional Plan		District Plan
School and contagious disease.....	140		316
Infant welfare and prenatal.....	152		226
Tuberculosis.....	101		98

MINNESOTA

Clinical Club Organized.—The younger physicians of Minneapolis have organized the Minneapolis Clinical Club and elected the following officers: president, Dr. Stanley R. Maxeiner; vice president, Dr. Clifton A. Boreen, and secretary-treasurer, Dr. Floyd O. Woodward.

Forty Fellows Enrolled.—The Mayo Foundation of the University of Minnesota has forty scholars and fellows enrolled for a full three years' course leading to a graduate degree. These men get an annual allowance, which is paid out of the endowment fund of the foundation.

Personal.—Dr. C. L. Martin has resigned his fellowship in the Mayo Foundation, Rochester, to take charge of the surgical work at a hospital in Wayne, Neb.—Dr. J. C. McRae has been granted a leave of absence for one year by the Mayo Foundation to accept a commission with the American Red Cross.

MISSOURI

Personal.—Dr. Eugene Lee Myers has resigned from the staff of the St. Louis College of Physicians and Surgeons.—Dr. Harry L. Ratliff, Webb City, superintendent of the Jackson County Tuberculosis Hospital, has resigned.—Dr. Owen P. McPherson, Kansas City, has recently received the Medal of the First Order of St. Sava, from the Serbian government.—Dr. David Wise, Joplin, was seriously cut and bruised about his head and shoulders, March 28, when another automobile collided with his coupé.—Dr. Karl E. Baker, Carthage, has been appointed commissioner of health for Jasper County.

State Society Meeting.—The sixty-third annual meeting of the Missouri State Medical Association was held in Jefferson City, April 6 to 8, under the presidency of Dr. Nimrod P. Wood, Independence. St. Joseph was selected as the next place of meeting and the following officers were elected: president, Dr. Wilson J. Ferguson, Sedalia; vice presidents, Drs. Robert L. Neff, Joplin, Thomas J. Rigdon, Kennett, Thomas Chowning, Hannibal, W. C. Taylor, St. Louis, and James Q. Chambers, Kansas City; secretary, Dr. Edward J. Goodwin, St. Louis (reelected); treasurer, Dr. J. Franklin Welch, Salisbury, and delegates to the American Medical Association, Drs. Franklin E. Murphy, Kansas City, Stuart L. Baysinger, Rolla, Charles R. Woodson, St. Joseph, and Elsworth S. Smith, St. Louis. The association adopted a resolution asking the governor and state legislature to establish a hospital at Columbia as part of the Missouri University Medical School to offer four years' work instead of the two years' course in the present university hospital.

NEW YORK

Health Conference Postponed.—The annual conference of health officers, which was to have been held June 22 to 24, has been postponed and will probably convene in September.

Personal.—The home of Dr. Joseph A. Blake, Tarrytown, was destroyed by fire on April 10, causing damage estimated at \$100,000. Dr. Blake's hands were severely burned while he was endeavoring to prevent the spread of the flames.

Report of State Hospital Commission.—The annual report of the state hospital commission for the last fiscal year shows that in spite of the fact that \$1,033,380 was spent last year for new construction, repairs and improvements to the institutions belonging to the state, the overcrowding is still 21 per cent. beyond their certified capacity.

Drive for Mental Defectives.—A drive to raise \$250,000 has been begun by the Home and Farm Institution for Mental Convalescents, Inc., with headquarters at 198 Broadway. Twenty-five nonsectarian organizations are taking part in the campaign. A site in Sullivan County has been donated by Joseph B. Olidort who is heading the campaign.

Hearing on Narcotic Drug Bill.—A hearing on the bill of Senator Cotillo was held before the senate health committee on April 15, at which the bill met with a good deal of opposition from certain representatives of the medical profession. The bill is in line with the federal law and forbids the prescribing of narcotic drugs to addicts in the regular course of practice. The measure was endorsed by the house of delegates of the Medical Society of the State of New York at its recent meeting.

Health Centers Approved.—The New York State Charities Aid Association has passed resolutions endorsing the Sage-Machold bill, now pending in the legislature, which provides for a comprehensive extension of the public health work of the state through the establishment of a statewide system of health centers, with an appropriation of state funds to supplement the expenditures made by communities in carrying on this work. The purpose of the bill is to take modern medical, laboratory, hospital and dispensary facilities to the doors of the people of moderate means and those who live in rural and industrial communities.

New York City

Dispensary Clinical Society Organized.—The medical and surgical staff of St. John's Hospital, Brooklyn, have organized the dispensary Clinical Society at St. John's Hospital with Dr. Harry P. Mencken, Flushing, chief of the dispensary service.

Association of Tuberculosis Clinics Meets.—This organization met in the New York Academy of Medicine on the afternoon of April 14. Among the speakers were Drs. Isaac Ogden Woodruff, James Alexander Miller, Alfred F. Hess, Dwight C. Martin and Geza Kremer.

Postgraduate Fund Grows.—The endowment committee of the New York Post-Graduate Medical School and Hospital announces that it has raised \$610,000 of the \$2,000,000 needed. The committee has resolved on intensified efforts to reach the goal set. The present campaign has drawn much attention to the lack of opportunity for graduate study for men of moderate means as contrasted with the provisions made for undergraduate study for poor boys.

Personal.—Dr. Seth M. Milliken, who was recently sued by a patient for \$200,000 for alleged false imprisonment in the psychopathic ward of Bellevue Hospital, has been exonerated by a supreme court jury.

Dr. H. Holbrook Curtis is seriously ill at his home on Central Park West.—Dr. George E. Brewer was shot and wounded in the leg by the man who killed Dr. James W. Markoe in St. George's Protestant Episcopal Church, April 18.—The National Academy of Science, at its annual meeting, April 22, conferred a gold medal on Dr. Alexis Carrel.—Dr. Benjamin Jablons has returned after an absence of five years during which time he served with American Ambulance Hospital, Paris, and later with the American Expeditionary Forces in France.—Dr. Bruno S. Horowicz, assistant sanitary superintendent of the Staten Island Health Department, has applied to the courts to have his name changed to Bruno S. Harwood.—Dr. Louis Berlin, Bay Ridge, has been cited by the French government as Officier de l'Académie with silver palms.

OHIO

Clinic for Venereal Diseases.—Cleveland announces that it will open a clinic for the diagnosis and treatment of venereal diseases at Fairview Park Hospital, May 25.

Drug Suspects and Drugs Seized.—In a drug raid in Toledo, April 8, city detectives seized \$30,000 worth of morphin and opium and arrested a woman and four men accused of smuggling these drugs from Canada.

Medical Building for Columbus.—Plans have been drawn for a medical office building to be erected on East State Street, Columbus, just east of St. Francis Hospital at an estimated cost of \$250,000. The building will be a four story, fireproof structure containing eighty offices.

Graduate Courses in Medicine and Surgery.—Western Reserve University School of Medicine, Cleveland, has announced courses of two months' duration in medicine and surgery during next June and July. Satisfactory completion of the courses by graduates in medicine will establish credits toward the A.M. degree in medicine.

State Association Meeting.—The seventy-fourth annual meeting of the Ohio State Medical Association will be held in Toledo, June 1 to 3, under the presidency of Dr. James F. Baldwin, Columbus. The annual orations will be delivered by Dr. Lewellys Franklin Barker of Johns Hopkins University on "High Blood Pressure, Its Causes and Management," and by Dr. Hugh Cabot, Ann Arbor, formerly of Boston, on "Non-Tubercular Infections of the Kidney."

County Buys Hospital.—The sale of the Springfield Lake Tuberculosis Sanatorium was consummated March 23, when Summit County purchased the interests of the other joint owners, Mahoning, Stark, Columbiana and Portage counties. For their respective shares, Mahoning received \$90,690.29; Stark, \$80,011.21; Columbiana, \$44,038.32, and Portage, \$25,068.95. Each county is given a year in which to remove its patients with the exception of Stark which has been given two years. Each county will also pay a weekly rate for its patients remaining during this period.

Personal.—Dr. George W. Wood, Wilmington, has been appointed resident physician at the Ohio Soldiers and Sailors Orphan Home, Xenia.—Dr. Robert H. Grube, Xenia, has been elected president of the Association of Health Commissioners of Southwestern Ohio, and Dr. Charles H. Tate, Dayton, has been elected secretary.—Dr. Delos W. Hogue has been appointed medical supervisor of the public schools of Springfield.—Dr. Rollin D. Worden, Ravenna, has been appointed commissioner of Portage County exclusive of Ravenna City.

Occupational Diseases Must Be Reported.—An amendment to the occupational disease reporting law, which becomes effective May 4, provides a penalty for physicians who refuse or neglect to report occupational diseases to the state board of health. By the terms of this bill, any physician who is attending or called to visit a patient whom he believes to be suffering from lead poisoning, poisoning from phosphorus, arsenic, brass, wood alcohol, mercury or their compounds, from anthrax, compressed air illness or from such other occupational diseases or ailments as the state department of health shall require to be reported, must make such reports to the state health commissioner within forty-eight hours from the time of the first visit, giving the name, address and occupation of the patient, the name and address in business of the employer, and the nature of the disease. It further establishes a penalty for the neglect or refusal to obey this law, a fine not to exceed \$100 or imprisonment not to exceed ninety days. These reports are to be made on the standard schedule blanks provided and distributed by the state department of health.

Cincinnati

Trachoma.—Dr. Oscar M. Craven, medical director of the health department of Cincinnati, reports that forty-two positive cases and twenty-four suspected cases of trachoma have been found in the city.

Physicians Honored.—Drs. Byron Stanton, Stephen C. Ayres, John C. MacKenzie and A. O. Mathews were made honorary members of the Cincinnati Academy of Medicine at its meeting April 5. Dr. Stanton has been a member of the academy for sixty-three years.

Illegal Practitioners Prosecuted.—It is reported that E. C. Branch was convicted, March 24, 1920, in the municipal court of Cincinnati, of the illegal practice of medicine and surgery. He was fined \$50 and costs.—Michael Jordan was found guilty of the illegal practice of medicine and was fined \$100 and costs by the municipal court of Cincinnati.

Organ of Academy of Medicine Appears.—The first issue of the *Cincinnati Journal of Medicine*, the official organ of the Cincinnati Academy of Medicine, has appeared under the editorial charge of Dr. Charles L. Bonifield. The initial number carries, practically in full, the report submitted by a special committee of the Cleveland Academy of Medicine outlining a comprehensive plan for the extension of functions and activities of the local medical society.

PENNSYLVANIA

Coeducation at the University of Pennsylvania.—An official communication from the University of Pennsylvania refers to the item published in Pennsylvania news, in *THE JOURNAL* of March 27, conveying the idea that the faculty is opposed to coeducation. The statement says that the news item is a gross exaggeration and relates the facts as follows: "One of our classes adopted a resolution stating that the class was opposed to coeducation in the school of medicine and desired to be so recorded. No such action has been taken by the other three classes and no objection has been raised by any member of our faculty to the best of my knowledge and belief."

Renew Fight on Hospitals.—The Anti-Sectarian Appropriations Association's fight against payment of state money to alleged sectarian hospitals and homes was renewed April 8. Willis Collins of Norwood, secretary of the body, brought mandamus proceedings in the Dauphin county court, Harrisburg, to prevent State Treasurer Kephart's paying appropriations made by the legislature in 1919 to five institutions, including two in Philadelphia. Similar action was brought by Collins last August against more than sixty institutions, but the court sustained the Attorney-General's contention. The suits today are each against a single institution and raise the question of legality of appropriations to institutions on the ground that they are denominational or sectarian. The actions are against the Jewish Hospital Association of Philadelphia which was voted \$30,000; the Sisters of Mercy, who have charge of the Dubois Hospital, \$25,000; Duquesne University of the Holy Ghost of Pittsburgh, \$50,000; the Protestant Deaconesses, and Evangelical Lutheran body operating Passavant Hospital, Pittsburgh, \$32,000, and St. Timothy's Memorial Hospital and House of Mercy, Roxborough, an Episcopal institution, \$50,000. The Attorney-General's department accepted service of the papers and will file an answer in thirty days.

Philadelphia

Northern Medical Association Meets.—The seventy-fourth anniversary of the Northern Medical Association will take the form of an Italian dinner to be held at Leoncavallo Café, May 20. The guests of honor will be the deans of the Philadelphia medical colleges.

Money for Insane Asked.—Dr. C. Lincoln Furbush, director of public health, submitted to the council an ordinance to appropriate \$50,000 for the department for the insane of the Philadelphia General Hospital. Ernest L. Tustin, director of public welfare, submitted an ordinance to transfer \$89,000 from the department of public welfare for improvements at the house of correction.

Civil Service Report.—The Civil Service Commission made public the result of examinations for the position of superintendent of the new Bureau of Hospitals in the Department of Health. This post, paying \$5,000 a year with free house rent, food and fuel, is one of the choicest places in the classified service. Only two of the twelve who took the examination obtained more than the required average of 70. They are Dr. John D. Jungmann and George C. Signor. Most

of those who took the examination also tried for the appointment as assistant superintendent, which pays \$3,000.

Fifty Thousand Dollars to Clean Up Streets.—To enable him to prosecute the war he has declared on municipal filth, Dr. C. Lincoln Furbush, director of public health, will ask the council for a large additional appropriation for the abatement of nuisances, which he will use in the elimination of insanitary conditions wherever they exist in the city. In making that announcement, Dr. Furbush indicated the sum he would ask would probably be \$50,000. There was need, he said, of from \$50,000 to \$100,000 for the abatement of nuisances in addition to the amount available for that purpose.

Personal.—Dr. Samuel W. Woodhouse, a graduate of Jefferson Medical College, has been appointed keeper of the collections of the Pennsylvania Museum and School of Industrial Art.—Dr. Ellen C. Potter, medical director of the Woman's Medical College Hospital, has been appointed chief of the division of child health, state department of health, to succeed Dr. Dorothy Child, resigned.—Dr. Joseph S. Neff, former director of public health and charities, has resigned as a member of the advisory council of the state health department, as he sails for Europe shortly.—Dr. William Hewson has been appointed electrocardiographist at the pathologic laboratory of the Philadelphia General Hospital.

TENNESSEE

New State Officers.—The eighty-seventh annual meeting of the Tennessee State Medical Association was held in Chattanooga, April 6 to 8, under the presidency of Dr. Andrew F. Richards, Sparta. Nashville was selected as the meeting place for 1921, and the following officers were elected: president, Dr. Leon L. Sheddin, Knoxville; vice presidents, Dr. George R. West, Chattanooga, for east Tennessee; Dr. Powell K. Lewis, Doyle, for middle Tennessee, and Dr. John J. Shea, Memphis, for west Tennessee; trustee of the journal, Dr. Charles J. Broyles, Johnson City (reelected); secretary, Dr. Olin West, Nashville (reelected), and treasurer, Dr. Joseph F. H. Gallagher, Nashville (reelected).—The eye, ear, nose and throat section of the association elected Dr. Edward C. Ellett, Memphis, chairman; Dr. Eldred B. Cayce, Nashville, vice chairman, and Dr. Louis Levy, Memphis, secretary.

CANADA

Military Hospital Closed.—The Saskatchewan Military Hospital, Moose Jaw, has been closed.

New Medical Building for Alberta University.—Draft plans for the erection of a new medical building for Alberta University, Calgary, to cost \$750,000, have been prepared.

Smallpox Ban Lifted.—The smallpox ban between Sault Ste. Marie, Ont., and Sault Ste. Marie, Mich., has been lifted so that it is not necessary for Americans visiting the Canadian side to be vaccinated or show certificates of vaccination before returning to the United States.

Extension Asked for Medical College.—A deputation from the University of Manitoba has petitioned the government to consider the provision of an extension to the medical college and to grant an appropriation this year for preliminary steps in connection with the new university at Tuxedo. The addition will be for laboratories.

Provincial Health Laboratory.—The government of British Columbia is establishing a provincial health laboratory, one branch of which will be in connection with the Vancouver General Hospital under the charge of Drs. John A. E. Campbell and Gibbs, and the other to be attached to the Royal Jubilee Hospital, Victoria, under the charge of Dr. Miller.

Personal.—Dr. Harold Orr, Medicine Hat, Alta., has been appointed by the provincial government to take charge of the administration of the venereal disease act, and clinics will be located at Edmonton, Calgary, and if need be at Medicine Hat and Lethbridge.—Dr. John Park has been reelected chairman of the Edmonton, Alta., Board of Health.—Dr. Wallace H. Cunningham has been appointed medical officer to the board of education of St. Catherine's, Ont.

GENERAL

Book Plates Wanted.—*THE JOURNAL* would be glad to receive copies of the book plates of physicians, of medical libraries, or of medical institutions, for use in a review of the subject. Copies of the book plates of noted physicians, now dead, will be especially appreciated. Mark envelop—"BOOK PLATE."

Health Authorities to Meet.—The eighteenth annual conference of state and territorial health authorities with the U. S. Public Health Service will be held in Washington, May 26 and 27.

Pediatric Society Meeting.—The thirty-second annual meeting of the American Pediatric Society will be held at the Moraine Hotel, Highland Park, Ill., May 31 and June 1 and 2, under the presidency of Dr. Thomas S. Southworth, New York City.

Medical School Recognized.—Inadvertently the name of the University of Illinois School of Medicine was omitted from the revision of Table D which appeared last week in the State Board Statistics. This medical school should have been included among those that are recognized in all states.

Social Hygiene Workers Needed.—The United States Civil Service Commission announces examinations for the following positions under the interdepartmental social hygiene board, receipt of application for which will close, May 4: director of bureau of the division or section of protective social measures, salary \$3,500 to \$4,500 a year; supervisor of protective measures, salary \$2,000 to \$3,600 a year; field agent, protective social measures, \$1,800 to \$3,000 a year, and special assistant agent, protective social measures, salary \$900 to \$1,500 a year. An examination will also be held on May 5 to fill positions of field agent in protective social measures, under the auspices of the board, with salaries ranging from \$1,200 to \$3,000. Further information may be obtained from the United States Civil Service Commission or from local civil service boards.

Vocational Rehabilitation.—Final legislative action has been taken in the Senate and House on the bill to establish vocational rehabilitation of persons injured or disabled in industry from any cause. This legislation will give federal and state aid to all persons who are suffering from physical defect, injury or disease, and who are partially or totally incapacitated from remunerative occupations. This aid will include the training and instruction of such persons for entering gainful occupations. The work is to be carried on under the direction of the federal board of vocational training. This board is to cooperate with vocational training boards of the several states, and the sum of \$1,000,000 is apportioned among the several states according to the population of each state. Each state is required to expend an amount equal to that expended by the federal government. The bill has passed both the Senate and House and awaits the report of the conference committee before going to the President.

Bequests and Donations.—The following bequests and donations have recently been announced:

University of Cambridge, England, a donation of \$100,000 for the erection and equipment of an institute for parasitological research, with an additional \$50,000 for its upkeep and maintenance, by Mr. and Mrs. A. P. Molteno.

The Ontario Honorary Advisory Council for Scientific Research has made provision for forty bursaries, studentships, and fellowships to be awarded to qualified science graduates who will prepare for a career in scientific research in connection with the natural resources of Canada.

Toronto General Hospital, a donation of \$250,000 toward lifting the debt on that institution, by Sir Joseph Flavelle.

Grant Hospital, Chicago, \$10,000, Alexian Brothers Hospital, Chicago, \$5,000 by the will of Jacob Birk.

Emergency Hospital, Chicago, \$400,000 by the will of Captain Charles Haines, St. Charles, Ill.

Henry Phipps Institute, Philadelphia, a donation of \$500,000 by the family of Henry Phipps.

Home for Aged Protestant Women and Home for Aged Persons, Nashua, N. H., each \$312,500, by the will of Miss Mary E. Hunt, Nashua.

St. Vincent's Hospital, New York City, \$100,000; Cancer Hospital, New York City, and Brooklyn Hospital, \$25,000; Brooklyn Home for Consumptives, \$20,000, by the will of Daniel J. Carroll, New York City.

Sheppard-Towner Bill.—National support and stimulation of maternity and child welfare are the objects of Senate Bill No. 3259, which has already had two readings in the Senate and has been referred to the committee on public health and national quarantine. This bill authorizes the appropriation of \$480,000 each year, \$10,000 to be paid annually to each state for the establishment and administration of boards of maternity and infant hygiene. In addition, it provides for the appropriation of \$2,000,000, increasing about \$400,000 annually after five years, to be apportioned to various states according to population, and not to be available unless matched dollar for dollar by state appropriation. The bill aims at cooperation with the several states in the promotion of the care of mothers and children; instruction in hygiene of maternity and infancy and the establishment of a federal

board of maternity and infant hygiene for the administration of the act and to make investigation, studies and reports on related subjects.

FOREIGN

Hospital at Omsk Closed.—The American Red Cross Hospital at Omsk, Siberia, has been evacuated and the patients taken to the Cadetsky Corpus Hospital, Omsk. During the nine months' existence of this hospital, 6,009 patients received treatment.

The Lannelongue Prize.—Prof. D. Giordano of Venice has been invited to be a member of the jury to award the Lannelongue prize (5,000 francs and a gold medal) offered by the French Surgical Association to the surgeon who has made the greatest discovery or done the most important work of the preceding five years.

Rockefeller Foundation Donation to Vienna Sufferers.—In response to a telegram from Dr. Linsly R. Williams of Johns Hopkins University, in which he states that more than 3,000 physicians are destitute and only 200 of the most pitiable cases can be taken care of by the American fund, the Rockefeller Foundation has made a donation of \$10,000.

Hospital Wing Named for Red Cross Worker.—One of the wings of the new municipal hospital, Lens, France, has been named after Miss Ella Harris, Philadelphia district manager of the American Red Cross, in that district of devastated France. The other three wings of the hospital are named after Premier Clemenceau, Marshal Foch and the mayor of Lens.

Epidemic Diseases.—Typhus fever is said to be ravaging eastern Galicia. During January and February 45,000 cases were reported.—Cholera and dysentery have broken out in Feodosia, Sebastopol and other cities of the Crimea, in addition to typhus fever, which is already epidemic. Sebastopol is virtually without water as it is dependent on a distilling plant which is out of service on account of lack of fuel.

Personal.—It is reported that Dr. Lorin A. Shepard, held as hostage by Turks after the withdrawal of a French relief column from Aintab, has been released.—Dr. L. W. D. Jackman, said to be a medical missionary at Sadiya, Assam, is reported to have been sentenced to two years' imprisonment for having shot and killed Major H. D. Cloete. Evidence was produced to show that Dr. Jackman committed the deed on hearing his wife's confession of infidelity.

Lectures on Tuberculosis in Children.—A special course on tuberculosis in children will be given at the Hospital for Sick Children, 149 Rue de Sèvres, Paris, May 4 to June 12, by Drs. H. Méry, P. Armand-Delille and L. Girard of the hospital staff. Lectures will be delivered at 5 p. m. on three days in each week, Tuesday, Wednesday and Thursday, and will embrace discussions of the etiology, pathology, varieties, diagnosis, prevention and treatment of the disease.

Child Welfare Work in Belgium.—A national children's bureau has been established in Belgium. The bureau is directed by a board of forty members, called the "Conseil supérieur des œuvres de l'enfance." This board has the decision on all questions relating to the protection of children; it issues orders concerning the functions of subsidized agencies; it takes necessary measures for the protection of children within the limits of the law; and determines the use of funds at the disposal of the bureau.

Taking Medicines Out of Poland.—Health Commissioner Louis E. Van Norman, at Warsaw, reports that grave concern is being manifested by the Polish Medical Association over the large amount of medical supplies that are constantly being taken out of the country both east and west. The country women, who formerly brought in constant supplies of herbs to the drug stores in Warsaw, are reaping fortunes by selling their agricultural products at high prices, so that they no longer bother with selling herbs. The medical association is preparing a memorandum to the government asking for the infliction of severe penalties for taking medical supplies out of the country.

New Archives for Internal Medicine Launched in Vienna.—A bulky journal of 210 pages, 6 by 10 inches, has reached us as the first issue of the *Wiener Archiv für innere Medizin*, published by twenty-four internists connected with the universities of Vienna, Prague and Innsbruck. Profs. W. Falta and K. F. Wenckebach (Frankgasse 2, Vienna) are the editors. The *Archiv* is to be issued irregularly, thirty to forty printed forms forming a volume; subscription price 54 marks. Urban and Schwarzenberg, Maximilianstrasse 4.

Vienna, are the publishers. The six articles in the first number are on the pathology of the lungs, circulation, vegetative nervous system and on palpation of the pulse. They will be reviewed in the foreign literature department.

Tribute to Majocchi.—Prof. Domenico Majocchi of the chair of skin diseases and syphilis in the University of Bologna soon completes his fortieth years' incumbency, and his pupils and other friends are planning to present him with a gold medal on the anniversary. An appeal has been issued for contributions, signed by the president of the Italian Società di dermatologia e sifilografia, the president of the Associazione professionale dei dermosifilografi italiani, the president of the Ordine dei medici, the rector of the university and the head of the medical faculty and of the local medical society. The secretary is Prof. G. Pini, Via S. Stefano 18, Bologna. The tribute is to be a feature of the annual meeting of the Società italiana di dermatologia e sifilografia which convenes at Bologna June 6. The list of Majocchi's works fills about half a column in the Surgeon-General's Catalogue.

Deaths in Other Countries

Baron Kanehiro Takaki, M.D., formerly inspector-general of the Japanese navy and leader in military hygiene, especially in the eradication of beriberi from the navy. He studied medicine in England in the seventies and visited the United States in 1905. Honorary degrees were conferred on him by Columbia and the University of Pennsylvania among others, and he lectured in this country. His work "Military Hygiene in the Japanese Navy" was published at New York in 1906.—Dr. A. Ceradini, professor of bacteriology at the University of Turin and president of the Reale Società d'igiene, aged 44.—Dr. P. Regard of Geneva, aged 62.—Dr. Ricardo Mesa Torres, a prominent physician of Santiago, Chile.—Dr. R. Schmucker, medical head of the Rudolf Children's Hospital, Vienna, aged 67.—Dr. L. Hauser of Darmstadt, aged 75.—Dr. E. Burchard, a neurologist of Berlin.—Dr. M. Stolz, professor of gynecology at the University of Graz.—Dr. M. Siegfried, professor of physiologic chemistry at the University of Leipzig.—Dr. T. Senise, professor of medical pathology at the University of Naples, author of works on the symptomatology of the respiratory and cardiovascular systems, and senator, aged 72.—Dr. M. Fürbringer, professor of anatomy at Amsterdam, Jena and Heidelberg in turn, aged 74.—James Pointon, Southampton, England; M.R.C.S. (Eng.), L.R.C.P. (Lond.), 1878; aged 69; senior medical officer of the Cunard Steamship Company; senior house surgeon to the Children's Infirmary, Liverpool, and honorary medical officer of the North Dispensary, Liverpool; surgeon of the Steamship *Royal George*; died at sea, April 11, from heart disease, and in accordance with his wishes, was buried at sea.

LATIN AMERICA

Leprosy in Venezuela.—According to the last report of the Office of Public Health of Venezuela there was a total of 720 lepers isolated in the two leprosariums of that country on Sept. 30, 1919.

Personal.—Dr. Pedro Alemán is now making a professional visit to New York City.—Dr. F. Vallarino, one of the physicians of the Santo Tomás Hospital of Panama, is now on his wedding trip in New York City.

Eugenics in Uruguay.—A bill has been introduced in Uruguay according to which no person will be able to marry unless he previously obtains a physician's certificate, showing the applicant is free from chronic, communicable disease.

International Sanitary Conference.—According to the provisional program for the Sixth International Sanitary Conference of the American Republics, to be held at Montevideo, Dec. 12-20, 1920, the following subjects will be discussed: sanitary laws and regulations adopted by the different countries since the fifth conference; enforcement of resolutions adopted at preceding conferences; report of the contagious diseases most prevalent in the different countries; measures adopted to prevent the introduction and the spread of bubonic plague; prevalence of cerebrospinal meningitis, infantile paralysis and lethargic encephalitis; present status of the campaigns against tuberculosis, yellow fever, malaria, trachoma and hookworm disease; data relative to leprosy and the measures taken to prevent its spread; present status of the campaign against venereal diseases; organization of the quarantine service in the different countries, and vital statistics of the different countries.

Government Services

Copies of Report of the Surgeon-General Not Available

According to law, only 2,500 copies of the report of the Surgeon-General can be printed, and additional copies cannot be printed without a special act of Congress. We are informed by Surgeon-General Ireland that all of the copies of the 1919 report have been distributed, and that it is impossible to obtain a special act for the printing of additional copies at this time.

The New Medical Reserve Corps

Commissions in the new Medical Reserve Corps are issued by the War Department only to those former medical officers who have applied either by means of the usual Form 150, accomplished at the time of discharge, or by formal application by letter to the Adjutant-General or Surgeon-General. Those who had service during the World War and who have not yet received commissions, should, if they desire to become members of the new Medical Reserve Corps, make application therefor by letter to the Adjutant-General of the Army.

The Medical Veterans of the World War

During March, 1920, 116 new members were admitted. The total membership now is 2,827.

Building for Army Medical School

The Army appropriation bill contains a provision for the expenditure of \$500,000 for suitable buildings to be used by the Army Medical School on the Walter Reed Hospital grounds at Washington, D. C. It is left to the discretion of the Secretary of War and the Surgeon-General to determine the kind and character of such buildings. The bill carrying this appropriation has been favorably reported to the House of Representatives by the committee on military affairs. The same bill also contains a provision for the erection and completion of buildings at the Letterman General Hospital, San Francisco, in the amount of \$94,900.

Work on Army Medical Center

Work on what is expected to be the largest medical center in the country will be started at Walter Reed General Hospital when plans now being drafted and calling for the assembling of the army medical school, nurse school, medical museum and library, at an estimated cost of \$10,000,000 are put into effect, it was announced yesterday. As the commencement of the project depends on congressional appropriations, it will probably be late in the summer before the erection of the army medical school building, the first of the proposed structures, will be begun. An appropriation bill for \$500,000 is now pending before Congress as the initial sum to cover the cost of this building.

It is proposed to purchase 40 acres of land to the north and west of the present hospital site and Congress has granted \$350,000 for its purchase. The plans also call for the building of additional wings to the present main building. The work of medical reconstruction and physiotherapy will be carried on in the enlarged institution and an adequate headquarters will be provided for the entire hospital corps. When completed, the enlarged hospital established on a permanent basis will accommodate from 500 to 700 beds or more.

The main purpose of enlarging Walter Reed is to provide a central point for the entire medical work of the army.

With this idea in mind, medical authorities of the army will be able to carry out a plan of gathering together all the army medical agencies, the need for which has been felt for many years.

Foreign Letters

PARIS

March 18, 1920.

Vaccines in Surgical Affections

At a recent session of the Société de chirurgie de Paris, there was an interesting discussion on the employment of vaccines in the treatment of carbuncles, especially by the method of Pierre Delbet. The latter combines Pasteur's method of attenuated cultures with the modern method of killed cultures. He found it possible by this means to inject a considerably larger dose, several billions of micro-organisms, at one time. Despite the massive dose, he has never observed any reaction analogous to that described by Wright as the negative phase, which Delbet thinks is the result of an excessive initial dose. On the contrary, certain toxic reactions were observed, often very violent, and despite their intensity, these were found to constitute a good omen. In the process of aging, the toxicity of the culture is probably attenuated though not entirely destroyed. After some attempts, Delbet fixed on 4 c.c., representing about thirteen billions of organisms, as a safe and effective dose. The vaccine is, naturally, a stock vaccine of streptococcus, staphylococcus and *Bacillus pyocyaneus* (the last in great abundance: eight billions). Delbet believes it unnecessary to use the specific micro-organism and, like Wright, he has not only abandoned autogenous vaccines, but he even questions whether better results are not obtained with a vaccine prepared from cultures of a micro-organism other than that which is the causative agent in a given case. The method has been employed since 1913, since which time no case of carbuncle in Delbet's service has been treated by surgical incision; boils, lymphangitis and erysipelas also respond very promptly to this treatment.

Professor Hartmann had occasion to employ the vaccine on himself for axillary adenitis. The after-pain was moderate, but for twenty-four hours the arm was virtually paralyzed. It seems to him that a crucial incision is indicated in certain advanced cases: in fact, in any case such intervention exerts a sedative influence on the pain.

Dr. Robineau found that on the day after injection the pain had subsided, palpation revealed that the carbuncle had decreased to half its original size, and the peripheral inflammation had disappeared. Recovery is usually complete in ten days, a distinct advantage over surgical treatment, by which relief from pain and recovery are not so promptly obtained. Dr. Grégoire recited his experiences with the vaccine in seventeen cases of subacute and acute osteomyelitis, leaving the severe toxic forms out of discussion. Fourteen resulted favorably, one was treated only recently, and two cases were partial failures in that sequestrums had formed. In some cases in which diffuse suppuration apparently threatened a joint, Dr. Grégoire made several punctures; the puncture fluid was at first frankly purulent, but gradually became of a viscous, albuminous character. In all cases, the temperature dropped in a few days after treatment, and the general condition improved rapidly. Recovery was effected in from thirteen to 178 days. One half of the patients were well in from thirty to sixty days. Dr. Ombrédanne declared that there should be left out of consideration, not only the severe toxic forms, but also the lighter acute forms susceptible of resolution, limiting ourselves to the acute suppurative forms which are usually treated by incision. In these cases he had variable results; besides some undoubted cures, he had complete failures and even disasters. Vaccinotherapy should be employed only after careful study of the indications. Professor Broca, on the contrary,

maintained that vaccines should be employed in severe cases, precisely because no harm can result. In a particularly bad case an extensive sequestrum was formed despite vaccino-therapy, and an operation was necessary, but the patient's life was saved, and Broca is persuaded that this was due to the vaccine.

The Printers' Strike and the Medical Press

From time to time in these pages have been recorded the difficulties with which the scientific press in general and the medical press in particular are now contending. For almost a month, these troubles have been aggravated by a strike of the printers. All of the large publishers of Paris have suspended. Fortunately, some of the medical journals are printed in provincial towns, and these are able to continue publication despite the strike. However, the *Presse médicale*, which is printed in Paris, has not been issued for three weeks, and the editors have announced that, depending on the circumstances and duration of the strike, they will later publish double numbers in the interests of their subscribers. Besides the periodical publications, many books are also delayed by the same strike.

The Red Cross Crusade Against Epidemics

At the first meeting of the General Council of the League of Red Cross Societies, held in Geneva, March 2-9, twenty-eight national societies were represented. It might be of interest to note that the same nations participated in the first council of the League of Nations. The general council decided to place at the top of the list of adopted resolutions the text of Article 25 of the constitution of the League of Nations, stipulating that the members of the League of Nations agree to encourage and further the establishment and cooperation of duly authorized voluntary national societies of the Red Cross. In the course of the session there was read an appeal from the League of Nations asking the Red Cross to combat the ravages caused by epidemics in central and eastern Europe. The council adopted a resolution expressing its full accord and complete sympathy with the suggestions, but pointing out that nothing could be done unless the necessary food, clothing and means of transportation were forthcoming. These the governments ought to provide; the League of Red Cross Societies on its part would seek the immediate extension of voluntary aid to the afflicted regions. The resolution closed with these words: This is the first time that, as the result of the collaboration of two great organizations, the League of Nations and the League of Red Cross Societies, there is born a more certain and adequate hope of the solution of the tragic problems that bring distress to the world.

LONDON

April 3, 1920.

The Association of Surgeons of Great Britain and Ireland

The formation of the Association of Surgeons of Great Britain and Ireland was described in a previous letter (THE JOURNAL, Feb. 21, 1920, p. 538). The first annual meeting will be held in London in May. The association exists for the "advancement of the science and art of surgery, and the promotion of intercourse and friendship among the surgeons of the United Kingdom." The number of fellows is not to exceed 250, and all must be engaged in purely surgical practice, in the teaching of surgery, or in surgical research. A fellow on ceasing to be a member of the active staff of his hospital will become a senior fellow, and will retain the privilege of attending the meetings. A general meeting will be held once a year, in May, in some town in the United Kingdom which possesses a university or medical school. The first meeting, and subsequently at least every third meeting, should be held in London. Fellows will be required

to speak—not read—their communications, and will be allowed not more than fifteen minutes. No reporters are to be present, and no reports of the meetings are to be sent to the journals or newspapers. The first general meeting will begin at the Royal College of Surgeons of England, when the president, Sir John Bland-Sutton, will deliver an address. There will be a discussion on "The Ritual of the Surgical Operation." The specimens in the war collection in the museum of the Royal College of Surgeons will be exhibited by Professor Keith. Sir George Makins will speak on selected specimens of wounds of vessels, and Sir Cuthbert Wallace on gunshot injuries of the abdomen. Two afternoons will be spent at various London hospitals, where cases will be shown and operations witnessed.

A "Dog's Protection Bill"

The defeat of a "dog's protection bill" introduced into the House of Commons last year has already been reported. Nothing daunted, the antivivisectionists have made another attempt. Sir F. Banbury, in introducing the bill, reminded the house that similar bills had been read a second time on three previous occasions. The present bill was in the form in which it left the "standing committee" last year. Sir Watson Cheyne moved an amendment declining to proceed with a measure which would impose a serious obstacle to medical research. He pointed out that the reason the dog was chosen was that of all animals its physiologic processes approached that of man. The surgery of the brain had been built up by experimenting on dogs. The experiments which caused pain were very few indeed. After an attempt to move the closure, the bill was talked out. In a letter to the *Times*, Dr. Thomas Lewis points out that almost the whole modern progress in diseases of the heart hinges on experiments on dogs. Auricular fibrillation was first recognized in man as a result of experiments on six London mongrels. The next step to be discovered was what fibrillation actually is. That cannot be done with observation on patients; it can be done only by observing the condition of the exposed heart of an animal. Thanks to the defeat of the bill last year, this work has been for twelve months in progress, and we are within sight of the goal. Already we have obtained a deeper insight into the condition. Dr. Lewis' views were quoted with effect by one of the opponents in the present bill.

The National Health Insurance

Like everything else after the war, national health insurance has become much more expensive than it was before. Dr. Addison, minister of health, has introduced a bill into Parliament increasing the benefits in the case of men from \$2.50 to \$3.75 a week for sickness and from \$1.25 to \$1.75 for disablement. In the case of women the benefit is to be increased from \$1.75 to \$3. These benefits necessitate an increased contribution of 6 cents a week for each insured person, of which it is proposed to derive 4 cents from the employer and 2 cents from the employee. Sanatorium benefit is to be taken out of the insurance act altogether, as the first stage of a comprehensive policy dealing with the whole problem of tuberculosis in all sections of the population.

The ministry of health is making an important addition to its machinery for the prevention of disease by appointing a new staff of outdoor medical officers with general duties, clinical and administrative. The new posts will be held either on whole or on part time basis, but only the duties of the whole-time officers are as yet defined. The latter, stationed in their various areas, will act in a clinical capacity, either as referees or as consultants. They will examine insured persons referred to them either by the practitioners working under the national insurance act or by the approved societies; they will advise either or both of these on the

question of capacity for work, and they will assist the physicians in matters of diagnosis or treatment. In their administrative capacity they will examine health insurance medical certificates and records, and conduct inquiries arising on any points relative to the treatment of the insured. It is proposed to appoint in the first instance eighteen whole-time officers for England and three for Wales, and to create also a certain small number of supervisory posts.

Medical Inspection from the Cradle to the Grave

The board of education has issued consolidated regulations relating to the special services of elementary education for promoting the healthy physical and mental development of children. The most important provision is one securing a continuity of medical records from elementary to secondary schools. This great reform was suggested in Sir George Newman's recent report. It means that a child will now have a complete health record through all school life until it is about to enter on its future career. Indeed, it may be that the record will go back to birth or even to the period of the antenatal clinic, for medical care is now exercised at day nurseries and nursery schools. Industry will thus be provided with records of fitness, and it will be possible for business firms to prevent the weak or diseased being employed in work endangering life or threatening the safety of others. Moreover, a complete national health census will be secured and the localization and spread of disease, its complications and after-effects worked out. The new order is thus, though a small measure, an integral part of a movement for the state control of health of great magnitude. A new link has been forged in a chain that will stretch from cradle to grave, as the subjoined tabulation demonstrates:

Antenatal Clinic	Voluntary Agencies or Local Authorities
Day nurseries till 2 years	Day nurseries
Nursery schools, from 2 to 5 years	Board of education
Public elementary schools, from 5 to 14 years	Board of education
Secondary schools, from 14 to 18 years	Board of education
Employment	National health insurance (Ministry of Health) Board of Trade, Home Office, etc.

Rewards for Professional Research

In the *Times*, Sir Ronald Ross, one of the deputation which (as stated in a previous letter) brought the question of rewards for scientific discoveries before the government, returns to the subject. The proposal was that the state should expend a maximum sum of \$100,000, a year for giving thirty or more moderate life pensions to men whose medical researches have been of accepted general value to the public without being remunerative to themselves. Owing to the number of the pensions and the small amounts of many of them, not only major discoveries but also much minor good work would receive recompense. At present, the Medical Research Committee dispenses subsidies for research, but that is a different matter. Mr. Balfour, who received the deputation, raised the difficulty that it was often hard to decide who had made the particular discovery. Sir Ronald Ross points out that such difficulties occur in the case of almost every kind of reward—when learned societies give medals, when the Royal Society elects new fellows, when the Nobel prizes are bestowed, and even when any state grants titles and honors. If the mere difficulty of selection is a bar to rewards, then scarcely any rewards at all can ever be bestowed. But in practice it is found that the difficulty can easily be overcome by keeping detailed registers of the work of all possible candidates, and by delegating the task of selection to competent committees. Even if an error is sometimes made—if a reward is given to the second best or third-best man—no great harm will be done, because in fact scientific discoveries are generally made by several persons, all of whom deserve the gratitude of the community.

Deaths

James Wright Markoe * New York City; College of Physicians and Surgeons in the city of New York, 1885; aged 58; a Fellow of the New York Academy of Medicine; consulting gynecologist to Vassar Brothers' Hospital, Poughkeepsie; consulting surgeon to the Neurological Institute and Caledonian Hospital, Brooklyn, and director and chief surgeon of the first division of the Lying-In Hospital of the City of New York; was shot and instantly killed, April 18, in St. George's Protestant Episcopal Church, New York City.

Arthur Frank Wilhelmy * Decatur, Ill.; Cincinnati College of Medicine and Surgery, 1896; aged 47; major, M. R. C., U. S. Army; a member of the attending staff of St. Mary's and Macon County hospitals; a member of the Decatur Board of Health; during the war with Spain captain, Illinois National Guard; while driving in his automobile over a grade crossing, April 16, was struck by an Illinois Central train and instantly killed.

James Thomas Searcy * Tuscaloosa, Ala.; University of the City of New York, 1867; aged 80; from 1892 to 1919 superintendent of the Alabama Bryce Insane Hospital; a Confederate veteran; president of the Medical Association of the State of Alabama in 1892 and 1893, and of the American Medico-Psychological Association in 1912-1913; died at the home of his daughter in Tuscaloosa, April 6.

George S. Dare, Rising Sun, Md.; Jefferson Medical College, 1866; aged 77; a member of the Medical and Chirurgical Faculty of Maryland; founder and for several years president of the Cecil County Medical Society; a director of the Union Hospital, Elkton; state director of the Baltimore Central Railroad; died, March 24.

Daniel F. Everts, Romulus, N. Y.; Long Island College Hospital, Brooklyn, 1876; aged 76; a member of the Medical Society of the State of New York, and president of the Seneca County Medical Society in 1882; a veteran of the Civil War; health officer of Romulus for several years; died, April 11, from pleuropneumonia.

Adlia C. Stanley, Tillar, Ark.; St. Louis College of Physicians and Surgeons, 1898; aged 67; a member of the Arkansas Medical Society; president of the Bank of Tillar, and formerly secretary and treasurer of the Good Bar Shoe Company, St. Louis; died in a hospital in Little Rock, March 25, from cerebral hemorrhage.

Frederick William McDonald * Wylam, Ala.; Birmingham (Ala.) Medical College, 1905; aged 40; once president of the Jefferson County Medical Association and a member of the medical staff of the Tennessee Coal, Iron and Railroad Company; died in an infirmary in Birmingham, April 6, from pneumonia.

George Egbert Fulton, Bluffton, Ind.; Miami Medical College, Cincinnati, 1878; aged 64; a member of the Indiana State Medical Association; a member of the state legislature in 1889 and 1891; local surgeon of the Toledo, St. Louis and Western Railroad; died, April 2, from pneumonia following influenza.

Daniel Arthur Chapman, Republic, Pa.; College of Physicians and Surgeons, Baltimore, 1907; aged 34; a member of the Missouri State Medical Association; a medical officer of the Second Missouri Infantry, with Mexican Border service in 1916; died in a hospital in Pittsburgh, April 5, from pneumonia.

Rozier Clageth Bayly * Alexandria, Va.; Georgetown University, Washington, D. C., 1905; aged 38; lieutenant, M. C., U. S. Army, and discharged, June 16, 1912; died in the Episcopal Eye, Ear, Nose and Throat Hospital, Washington, D. C., March 28, three days after an operation for mastoiditis.

Henry Brooks Baker, Ypsilanti, Mich.; Bellevue Hospital Medical College, 1866; aged 82; superintendent of vital statistics and secretary of the Michigan State Board of Health for nearly thirty-five years; once vice president of the American Social Science Association; died, about April 3.

Joseph Alexander Dambourges Jacques, Marlboro, Mass.; Montreal School of Medicine and Surgery, 1901; aged 43; for many years a member of the board of trustees of the Marlboro Public Library; died, April 4, from heart disease.

* Indicates "Fellow" of the American Medical Association.

Joseph Simms, New York City; Eclectic Medical College of the City of New York, 1871; aged 86; a veteran of the Civil War; a member of the Anthropological Institute of Great Britain and Ireland; a specialist in physiognomy; died, April 11, from cerebral hemorrhage.

S. M. Mosely, Huntington, Ark. (license, state medical board, Arkansas, 1903); aged 54; mayor of Huntington; died in the Sparks Hospital, Fort Smith, Ark., March 29, from the effects of a gunshot wound of the abdomen, believed to have been accidentally inflicted.

Milton V. Cunningham, Youngstown, Ohio; College of Physicians and Surgeons, Chicago, 1894; aged 52; for two years city physician of Youngstown; a member of the staff of St. Elizabeth's Hospital; died at Santa Ana, Calif., March 24, from cerebral hemorrhage.

Justin Adfer Walling, Millbridge, Me.; Medical School of Maine, Brunswick and Portland, 1882; aged 51; a member of the Maine Medical Association, and president of the Washington County Medical Association; died recently.

Fred Charles Hunt, Girard, Ohio; University of Buffalo, 1897; aged 44; lieutenant, M. C., U. S. Army, and discharged, Jan. 11, 1919; died in St. Elizabeth's Hospital, Girard, March 20, as the result of middle ear disease.

Chauncey E. Koon, Grand Rapids, Mich.; Chicago Medical College, 1873; aged 76; visiting physician to Butterworth Hospital and a member of the staff of the Detention Hospital; a veteran of the Civil War; died, April 6.

Robert Lount, Hempstead, N. Y.; State University of Iowa, College of Homeopathic Medicine, Iowa City, 1881; aged 75; for twenty years health officer of Hempstead; died, April 5, from cerebral hemorrhage.

Robert Lee Long ♂ Atlanta, Texas; Memphis, Tenn., Hospital Medical College, 1902; aged 46; lieutenant, M. C., U. S. Army, and discharged, Dec. 21, 1918; was killed in a grade crossing accident, March 23.

Francis T. Overdorff, Johnstown, Pa. (license, Cambria County, Pa., 1885); a practitioner for forty-nine years; aged 79; a veteran of the Civil War; died in Johns Hopkins Hospital, Baltimore, April 5.

Benjamin F. Walker, Colerain, S. C.; Medical College of the State of South Carolina, Charleston, 1861; aged 87; for four years surgeon in the Confederate service during the Civil War; died, April 7.

John Peter Marshall ♂ Warren, Ohio; Jefferson Medical College, 1908; aged 37; a member of the American Academy of Ophthalmology and Oto-Laryngology; died, about April 5, from septicemia.

Harry Anderson Upshaw ♂ St. Louis; Marion-Sims College of Medicine, St. Louis, 1898; aged 42; lieutenant, M. R. C., U. S. Army; died in St. Anthony's Hospital, St. Louis, April 3.

George W. Seibert, Lebanon, Pa.; Jefferson Medical College, 1879; aged 65; for a time a member of the board of health of Lebanon; died in the Harrisburg Hospital, March 29.

Robert Sewell Johnston, Orange, Texas; Vanderbilt University, Nashville, Tenn., 1882; University of Nashville, Tenn., 1883; aged 57; died in San Antonio, about March 7.

Frederick Blecker Callin, Akron, Ohio; Ohio Medical University, Columbus, 1893; aged 63; who had been spending the winter in St. Augustine, Fla.; died suddenly, March 28.

John N. Thomas, Reed City, Mich.; Grand Rapids, Mich., Medical College, 1903; Hahnemann Medical College, Chicago, 1904; aged 37; died, March 29, after a surgical operation.

Herbert S. Hill, Springfield, Mo.; Rush Medical College, 1869; aged 76; a member of the Missouri State Medical Association; died in a hospital in Springfield, April 1.

James Mortimer Bodwell, Phenix, R. I.; Medical School of Maine, Brunswick and Portland, 1894; aged 51; a member of the Rhode Island Medical Society; died, March 25.

Eli L. Eberhard ♂ South Whitley, Ind.; Medical College of Ohio, Cincinnati, 1880; aged 62; local surgeon for the Nickel Plate and Vandalia systems; died, March 30.

John W. Nabersberg, St. Paul; Medical Department, University of Iowa, 1865; aged 91; a veteran of the Civil War; died, March 24, from hemorrhage of the bladder.

Charles Van Hook Ingle, Evansville, Ind.; University of Pennsylvania, Philadelphia, 1902; aged 41; died at the home of a relative at Los Angeles, recently.

Isaak Moskovich Zimmerman ♂ San Diego, Calif.; Imperial University, Warsaw, Poland, 1885; aged 56; died, March 15.

Goldsby King ♂ Selma, Ala.; Medical College of the State of South Carolina, Charleston, 1880; aged 63; died, April 5, from acute dilatation of the heart.

Edward Thayer Twitchell ♂ Ashmont, Boston; Harvard University Medical School, 1886; aged about 60; died, April 6, in Santa Barbara, Calif. -

Samuel Lowry Wiggins ♂ McKeesport, Pa.; Jefferson Medical College, 1873; aged 71; surgeon to the McKeesport Hospital; died, April 3.

James Keirl Gilder, Newberry, S. C.; University of the City of New York, 1878; aged 64; died in the Columbia, S. C., Hospital, April 6.

William O. Hitchcock ♂ Dallas, Ga.; Southern Medical College, Atlanta, Ga., 1889; aged 57; died, March 31, from cerebral hemorrhage.

Hiram H. Shafer, Alliance, Ohio; Western Reserve University, Cleveland, 1882; aged 65; died, March 31; from cerebral hemorrhage.

John William Dodson, Rochester, N. Y.; University of the City of New York, 1888; aged 55; died, March 24, from cerebral hemorrhage.

George Pitkin Cooley, New Britain, Conn.; Homeopathic Medical College of Pennsylvania, Philadelphia, 1862; aged 91; died, April 2.

Winfield Kennedy Sharp, Pendleton, S. C.; Louisville, Ky., Medical College, 1874; aged 74; a Confederate veteran; died, March 18.

Thomas R. Carothers, Rock Hill, S. C.; Medical College of Virginia, Richmond, 1877; aged 65; died, March 31, from heart disease.

William A. Yeagy, Dillsburg, Pa.; Jefferson Medical College, 1890; aged about 57; died about April 3, from malignant disease.

Abraham B. Bradford, Belleview, Tenn.; Vanderbilt University, Nashville, Tenn., 1881; aged 67; died, April 4, from pneumonia.

Robert F. Wichterich ♂ Cape Girardeau, Mo.; Barnes Medical College, St. Louis, 1899; aged 52; died in his office, April 2.

Vallandigham Bodey, Dayton, Ohio; Starling Medical College, Columbus, Ohio, 1895; aged 56; died, about March 23.

Theodore Pachali, Reading, Pa. (license, Berks County, Pa., 1881); aged 74; a practitioner since 1865; died, March 26.

Elmer E. Gible, Philadelphia; University of Pennsylvania, Philadelphia, 1893; aged 53; died, April 6, from pneumonia.

Frank Worthington Wilson, Muskegon, Mich.; University of Michigan, Ann Arbor, 1879; aged 65; died, March 21.

Royal Lee Hobbs, Reisterstown, Md.; Johns Hopkins University, Baltimore, 1918; aged 25; died, March 29.

Jeremiah A. Proctor, Union City, Ind.; St. Louis University, 1844; aged 90; died, April 7.

Marriages

LIEUT. ALBERT GOULD WENZELL, M. C., U. S. Navy, Washington, D. C., to Miss Emma Pettit of Harrisburg, Pa., on board U. S. *Mercy*, at Brooklyn Navy Yard, April 8.

THOMAS STEVEN CULLEN, Baltimore, to Miss Mary Bartlett Dixon of Baltimore and Easton, Md., at Princeton, Md., April 6.

WILLIAM AUGUSTUS DEAN, Tulsa, Okla., to Miss Fannie Belle Hamilton of Seneca, S. C., at Tulsa, April 3.

ALEXANDER F. ROBERTSON, Staunton, Va., to Miss Frances Sexton of Hazelhurst, Miss., March 26.

ALBERT VALE HUFFMAN, South Bend, Ind., to Miss Maude Tiner of Indianapolis, February 14.

OLIVER HAZARD PERRY PARRIGAN, Monticello, Ky., to Miss Mai Akers of Sonora, Ky., April 7.

LARCUS B. ALLEN to Miss Mary Vaughn Shealy, both of Alexander City, Ala., April 5.

MARSHALL BURR CATLETT to Miss Ethel Bercot, both of Fort Wayne, Ind., March 30.

DOUGLAS LAMAR HEAD, Concord, Ga., to Miss Adel Smith of Atlanta, Ga., March 25.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

SOME ADULTERATED OR MISBRANDED MINERAL WATER

Harris Spring Water.¹—The Harris Springs Water Co., Harris Springs, S. C., shipped some Harris Spring Water in January, 1917, from South Carolina to Georgia. Examination of this water by the Bureau of Chemistry disclosed *B. coli* in small quantities; the total number of organisms growing on agar at 37 C. exceeded 100 per c.c.; molds and liquefying organisms were also found. The government officials charged that the water was adulterated for the reason that it consisted in part of a filthy, decomposed, and putrid animal and vegetable substance. It was also declared misbranded as the quantity of the contents was not plainly and conspicuously marked on the outside of the package. In October, 1918, the company was found guilty and fined \$25.—[*Notice of Judgment No. 6613; issued March 22, 1920.*]

Sprudel Concentrated Spring Water.—The West Baden Springs Co., West Baden, Ind., in August, 1917, shipped a quantity of "Sprudel Concentrated Spring Water," which was adulterated and misbranded. Examination by the Bureau of Chemistry showed that six out of eight bottles examined contained bacilli of the colon group and the product was declared adulterated because it contained "filthy and decomposed animal or vegetable substance." It was declared misbranded because the label stated that the water was "fortified with some of the natural products of the water" when as a matter of fact it contained added salts not obtained from the West Baden Springs. Furthermore, it was declared misbranded because it was falsely and fraudulently represented as a treatment for gout, rheumatism, diabetes and obesity "whereas in truth and in fact it was not." In November, 1918, the company pleaded guilty and was fined \$100 and costs.—[*Notice of Judgment No. 6641; issued March 22, 1920.*]

American Apollinaris Mineral Water.—The Standard Bottling and Extract Co., Boston, in the name of the American Apollinaris Co., shipped in December, 1915, a quantity of "American Apollinaris Mineral Water" which was adulterated and misbranded. It was adulterated in that a product other than Apollinaris Water had been substituted in whole or in part for Apollinaris Water. It was misbranded, first because the label falsely and misleadingly represented to purchasers that the article was Apollinaris Water when it was not, and further, because the quantity of the contents was not plainly and conspicuously stated on the outside of the package. In September, 1919, the company entered a plea of *nolo contendere* and was fined \$25.—[*Notice of Judgment No. 6661; issued March 29, 1920.*]

Robinson Spring Water.²—The Robinson Springs Co., Pochontas, Miss., shipped in July, 1917, a quantity of Robinson Spring Water. The government charged that this article was misbranded because certain therapeutic or curative claims made on or in the trade package were false and fraudulent and applied knowingly and in reckless and wanton disregard of their truth or falsity. The false and fraudulent statements were such as to lead the purchaser to believe that Robinson Spring Water was effective as a remedy for Bright's disease, diabetes, dropsy, cystitis, gout, rheumatism, indigestion, kidney and bladder troubles when in truth and

in fact it was not. One C. L. Bradley appeared in the suit claiming the water as his property and denying that the therapeutic claims were false and fraudulent. Bradley averred that many reputable physicians had testified to the therapeutic value of this water in the treatment of the diseases for which he recommended it. Judge Jack in delivering his charge to the jury emphasized the fact that the government was not attacking the water as bad or unfit for use but was attacking the therapeutic claims made for it. In his charge Judge Jack had the following pertinent comments to make on the Food and Drugs Act:

"The Pure Food and Drugs Act is one of the best laws of its character placed on the statute books in many years. It simply means that a man shall correctly brand or label that which he ships in interstate commerce, that the purchaser must be informed of the character of the article bought, and must not be deceived as to its curative properties, in other words, that the drug must not be sold under false representations.

"Barnum, the veteran showman, used to say that the American people like to be humbugged. That is, perhaps, more or less true. Consequently, a man who deliberately bets his money on a shell game, or who invests his savings in a gold brick, receives, and is entitled to, little sympathy. There is, however, a class of people, not ordinarily over credulous or gullible in ordinary matters of business, who, when stricken with a fatal malady, like drowning men, grasp at straws, and fall easy victims to quack doctors and patent medicine fakers. Such a man, when told by his physician that his case is hopeless and his days numbered, against his own better judgment, tries one nostrum after another in the desperate hope that he may find a cure. Such a man is the more easily persuaded to buy an alleged remedy whose efficacy he may doubt if he knows that it is at least perfectly harmless. These remarks are made to impress on your minds the wisdom of the law and the importance of its strict enforcement.

"If the water in question has the qualities attributed to it by the owner, it is not only his right to so advertise it but is to the interest of the public that he should do so. On the other hand, if the water has not the qualities ascribed to it, then such false advertising by labels on the bottles should be suppressed, and the deception of the public should be stopped."

The jury returned a verdict for the government and on Feb. 25, 1919, a decree of condemnation and forfeiture was entered.—[*Notice of Judgment No. 6623; issued March 22, 1920.*]

Ferro-Manganese Regent Spring.—The Excelsior Springs Mineral Water and Bottling Co., Excelsior Springs, Mo., shipped in May, 1917, a quantity of "Ferro-Manganese Regent Spring." The product was declared misbranded because it was falsely and fraudulently represented "as a remedy for alcoholism, chronic rheumatism, dyspepsia, diabetes, Bright's disease, albuminuria, dropsy, sciatica and insomnia, when, in truth and in fact it was not." Furthermore, the quantity of the contents was not plainly and conspicuously marked while the label was so worded as to deceive and mislead purchasers into the belief that it was a natural mineral spring water when in fact it was an artificial carbonated water. In December, 1918, the company pleaded guilty and was fined \$15 and costs.—[*Notice of Judgment No. 6665; issued March 29, 1920.*]

Indoor Life and Tuberculosis.—There is every reason to assume that the habitual inhalation of air vitiated by dust, the products of respiration, combustion and decomposition, and by the possible presence of toxic fumes and gases, plays an important rôle in the causation of respiratory diseases. All the injurious effects are intensified when human beings are obliged to occupy rooms with an air supply insufficient for the proper oxygenation of the blood, and also when, because of inadequate floor space, contact infections are more frequent. As a result of these adverse conditions we note an undue prevalence of consumption, pneumonia and septic sore throat in crowded workshops, dwellings, prisons and, formerly, also in military barracks and on battleships.—G. M. Kober, *Pub. Health Rep.*, March 26, 1920.

1. This is the second case of misbranding of Harris Spring Water; the other case is described in Notice of Judgment No. 4441.

2. This is the fourth case of misbranding of Robinson Spring Water; the other cases are described in Notices of Judgment Nos. 4072, 4073 and 4667.

Correspondence

EXPERIMENTAL WORK ON CAUSATION OF LETHARGIC ENCEPHALITIS

To the Editor:—In THE JOURNAL, March 27, Dr. Simon Flexner published a comprehensive article on encephalitis lethargica. On page 868 he refers to the experimental work which my associates, Drs. Loewe and Hirshfeld, and myself have done on the etiology of the disease in transmitting it to rabbits and monkeys. In this reference he states that "Apparently they did not succeed in infecting those animals by inoculating the affected nerve tissues themselves." This is an error in statement, probably due to an oversight on the part of Dr. Flexner.

In the *New York Medical Journal*, May 3, 1919, we described the successful inoculation of a *Macacus rhesus* monkey with an emulsion of brain from an encephalitis patient. An emulsion of the brain of this animal was injected intracerebrally into another *Macacus*, and we reported that this animal developed a hemiparesis six days after the inoculation. Despite the period intervening between the inoculation and the development of symptoms, the paralysis was thought to have been due to hemorrhage following the injection, and we reported "lesion possibly traumatic." Subsequent study of this brain revealed that, in addition to the hemorrhage and necrosis, the typical vascular lesions of encephalitis were found, and we reported this observation in the *Journal of Infectious Diseases*, November, 1919. In the same article we also reported the successful inoculation of a rabbit with a filtrate of the other hemisphere of the same brain, which had been preserved in 50 per cent. glycerin for two months. We therefore feel that we have succeeded in infecting animals by inoculating the affected nerve tissues.

ISRAEL STRAUSS, M.D., New York.

"THE CAUSE OF ABSCESS OF THE LUNG AFTER TONSILLECTOMY"

To the Editor:—Dr. Clendening, in his article in THE JOURNAL, April 3, 1920, protests against the use of the motor-driven ether apparatus. He says: "These ingenious little mechanisms force ether into the posterior pharynx, under what is really a very high [sic] pressure." The instruments which I have used daily for years—the Yankauer and the Beck-Mueller instruments—produce *no pressure* in the posterior pharynx, as can be demonstrated by holding a piece of lint in the back of the throat. The ether enters the mouth through a curved cannula and is thrown against the buccal wall external to the molar teeth, and from there the current is thrown more upward than toward the posterior pharyngeal wall and the glottis. It sounds like a joke to hear one say that "the pressure balloons out the posterior pharyngeal space" and that it "impedes coughing." None of these things have ever occurred with the machines with which I am familiar. This apparatus enables the anesthetist to maintain a constant anesthesia, and thus aids materially the operator to do his work in a surgical manner. In the presuction and motor-driven-ether days a tonsillectomy was the dirtiest piece of surgery imaginable. Now it is a respectable procedure. The patients never vomit and they inhale less blood, less pus and less vomitus.

His second conclusion—that there is a "direct relation between the tonsil and the lung"—seems unwarranted. The Doctor's argument for a direct infecting channel from the tonsil to the apex of the lung does not seem at all convincing. The lung is enclosed in a serous sac, one portion of which covers the lung and the other the parietal wall, and there is

no possible way of having a direct infection without having a previous inflammation and adhesion of the walls of the pleura. One would conclude from the Doctor's inference that there is an unknown open lymphatic sewer drain direct from the tonsil to the apex of the lung. The case he cites to prove his contention certainly does not prove anything except that the whole bronchial tree is more or less of a reservoir for the infectious material which drops down from the mouth, the sinuses and the tonsils.

The relief of such cases as he referred to, i. e., a troublesome bronchitis relieved after removing infected tonsils, has been the experience of thousands of men. This knowledge is so common that many of the laity come to the specialist and ask to have the nose, tonsils and sinuses examined for a focus of infection. In a series of more than a thousand consecutive tonsillectomies done under local anesthesia by myself and immediate colleagues, there has not been a single instance in which so much as a bronchitis developed after the operations. It would seem, then, if such a serious infection was so frequent, and their path of infection such a straight channel, that certainly one out of a thousand of our cases might have shown some kind of infection.

As to the matter of stopping hemorrhage, we are scolded as maulers. If the Doctor knows of a *noli tangere* method of stopping a hemorrhage, please let us have it. It is a very simple matter to sew up a tonsillar cavity, and by properly placing one's sutures, a sufficient pressure can be brought to bear to control almost all postoperative hemorrhage. I have never seen a case of bronchitis nor lung abscess from sewing up a tonsil cavity. I, too, agree that unnecessary probing or sponging in the cavity is detrimental. He mentions one of Dr. Richardson's cases of lung abscess following the sewing up of a tonsil, and attributes the abscess to that operation. Did not Dr. Richardson give ether to stop his hemorrhage, and could not the abscess be attributed to either the ether or the insufflation of infected mucus and blood?

If the Doctor expects to "retain the confidence of the rest of the profession" he will have to give us more evidence of his "direct path from the tonsils to the lung," and he will have to *show* some of us men who have used the invaluable so-called pressure anesthesia apparatus for years without any evidence whatever of harm that it is really harmful.

OSCAR WILKINSON, M.D., Washington, D. C.

To the Editor:—An interesting article entitled "The Cause of Abscess of the Lung After Tonsillectomy" by Logan Clendening, M.D., appeared in THE JOURNAL, April 3. The argument is: Lung abscesses have occurred rather frequently of late years; motor apparatus for anesthesia has been used rather frequently of late years; therefore lung abscesses are caused by motor apparatus. Therefore motor apparatus are to be discontinued until we find that they are not to blame, on which finding they may presumably be used again. The author has nothing to say of the rather important question of measured pressure, of ether concentration, or of the precise point of delivery of the vapor. I have assisted at many hundred tonsillectomies done by insufflation anesthesia and have never witnessed "ballooning of the posterior space." Nor have I ever seen pressure per se impede coughing. The refutation of this absurd notion is thrust on one only too often in the presence of a reduction in the concentration of the anesthetic vapor.

One is impelled to ask: Wherein lies the peculiar viciousness of a motor apparatus, as compared with its predecessor, the foot bellows? Is it because it is electrical, complicated, rather more difficult to manage, and more expensive to buy and maintain? To insist on the discontinuance of motor apparatus implies the cessation of insufflation anesthesia. Inhalation methods alone remain. Ether by inhalation will

not maintain anesthesia in adults suffering tonsillectomies. More powerful agents must be employed. We are familiar with chloroform maintenance. We know its advantages and its dangers. Some of our best operators prefer this method in expert hands. As a routine, chloroform has been used with decreasing frequency. It is being replaced by ether insufflation.

I know of no better way to protect the patient against the possibility of lung abscess than a strict adherence to the correct details of a properly conducted insufflation method. These details are essentially as follows: The delivery of the vapor must be made intranasally through catheters which terminate below the base of the tongue, behind and below the tonsils and any subsequent hemorrhage. By this means, blood, saliva, and portions of tonsil are blown into the mouth away from the larynx. The volume of air delivered should be sufficient for the respiratory needs, from 15 to 20 liters a minute. The pressure should not exceed 30 mm. of mercury. The concentration of ether should remain between 60 and 70 mm. vapor tension.

The latter part of the article will give the nose and throat surgeon food for thought. It appears that there are cases of lung abscess in which motor apparatus have not been used. The familiar relationship between tonsil and lung must therefore account for this. The surgeon is told not to dabble in the denuded area (presumably the tonsillar fossa). He is also consoled with the thought that there is "no good reason for getting out every particle of tonsillar tissue," this being quite impossible unless done "at the first step of the operation."

PALUEL J. FLAGG, M.D., New York.

"PRONUNCIATION OF DUODENUM"

To the Editor:—The inquiry of a librarian (THE JOURNAL, April 10, 1920, p. 1040) as to how to pronounce a simple word like "duodenum," which can be found in any dictionary—and by any dictionary I do not mean a medical dictionary, but one by professional lexicographers and philologists—emboldens me to ask the question I have long had in mind: Why not a dictionary by the American Medical Association? Perhaps the librarian had looked in the regular dictionaries, and the physicians whom she heard using the word had never looked.

There are about half a dozen medical dictionaries on the market now, all covering the same field approximately, and there is little choice among them, although each publisher claims an advantage for his. In these days of efficiency and scarcity of paper, one dictionary ought to be enough for the medical profession in this country. Few of the existing dictionaries are bold enough to indicate clearly the quality of vowels, being content for the most part to point out the stressed syllables. The derivations of the words are variously given. Rarely a definition is poorly given or misleading. In one instance I recall having seen a technical word misspelled and correctly spelled in the same dictionary, and correctly defined in each place.

The ideal medical dictionary would be one edited by a board of lexicographers and philologists. The definitions would be originally supplied by specialists in various medical branches. The pronunciations would be clearly indicated by the use of all the diacritical marks and characters employed by regular dictionaries of the English language. The derivations of the words would be clearly explained, and when from the Greek the original type would be employed. If one is intelligent enough to appreciate Greek in Latin characters he would surely appreciate it in the original type. Unusual terms would have a reference to the original use.

A philologist's choice should be indicated in such words as anemia, anazemia; leucemia, leucaemia; leukemia, leukaemia; poik-, poek-, pek-, poic-, poec-, pecilocyte, spirochaeta, spirochaita, spirocheta. As well ask a lexicographer to diagnose a neoplasm under the microscope as to let the average medical man settle such spellings.

The abstractors of Current Medical Literature for THE JOURNAL, and the compilers of the splendid *Quarterly Cumulative Index* published by THE JOURNAL, are in excellent position to find all the new words used in medicine. Once such a dictionary has gotten under way, a yearly supplement could be furnished to each subscriber. In a five year period a new edition could be put out. "Why not?"

M. W. LYON, JR., M.D., South Bend, Ind.

TITLES TO HIDE THE IDENTITY OF DRUGS

To the Editor:—At its next meeting, the U. S. Pharmacopoeial Convention should consider the giving of technical names to those drugs the names of which are practically the same in English and in Latin, for the reason that the physician often wants to prescribe these drugs and does not want his patient to know what he is ordering. Such drugs include quinin, morphin, codein, cocain, strychnin, and there may be others that I do not at this moment recall. In this city "pulv. cinchonae fortior" is ordered when quinin is wanted. Outside of this city no one would know what was desired. I order erythroxylinæ when I want cocain; some druggists do not know what I want. As we have acetylsalicylic acid for aspirin, or acetphenetidin when phenacetin is wanted, so we should have technical names for the other drugs. I hope to be present at the convention for the revision, when it meets here. I hope it will give this matter careful consideration.

C. R. DUFOUR, PHAR.D., M.D., Washington, D. C.

[COMMENT.—We question the need for Pharmacopoeial titles for salts of quinin, morphin and cocain especially designed to hide the identity of these drugs from the patient. Patients who are sufficiently intelligent to recognize terms such as cocainæ hydrochloridum, morphinæ sulphas or quininæ sulphas may be trusted to know the identity of the drugs which they are taking—particularly since the Harrison Narcotic Law safeguards the use of narcotic drugs.—ED.]

THE OLD QUESTION: THE DISCOVERER OF ANESTHESIA

To the Editor:—In THE JOURNAL, April 10, 1920, Dr. S. Adolphus Knopf directs attention to the discovery of ether as an anesthetic agent by Dr. William T. G. Morton, and expresses the hope that a statue of that distinguished physician may be placed in the Hall of Fame.

While it is generally accepted that Dr. Morton made an independent discovery of ether as an anesthetic, and applied it practically at the Massachusetts General Hospital, Oct. 16, 1846, it is likewise believed that sulphuric ether was employed as an anesthetic by Dr. Crawford W. Long as early as March 30, 1842. On that occasion Dr. Long removed a growth from the neck of a Mr. James Venable, the original bill for that service being still in existence.

It would appear, then, that Dr. Long applied ether in practical use more than four years before Dr. Morton called attention to its anesthetic properties. Unfortunately, Dr. Long delayed in announcing his discovery, and to him no credit can be given for acquainting the world at large with this great blessing. But ample proof has been produced to show that the Georgia physician was the first to discover ether anesthesia, so that further argument on the subject would seem unnecessary. S. J. LEWIS, M.D., Augusta, Ga.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TUBERCULOSIS AMONG ESKIMOS—TREATMENT OF LEUKOPLAKIA

To the Editor:—1. Please give me reference or information relative to the frequency of tuberculosis among the Eskimos. 2. What can you say of the treatment of leukoplakia?

A. E. HUBBARD, M.D., Peoria, Ill.

ANSWER.—1. Franz Boas (Ann. Rep. Bureau Am. Ethnol. 6, 1884-1885) and E. W. Hawkes (Canada, Geol. Survey, Mem. 91, 1916) comment on the prevalence of infectious respiratory diseases among the Eskimos of Alaska and Labrador. Dr. Grenfell (Labrador, the Country and the People, New York, Macmillan Company, 1910) writes: "Consumption is the main enemy of these people who live here in one of the purest atmospheres in the world" (p. 178). "The worst enemy of the Eskimo is, again, tuberculosis, and from that in one form or another most of the people die" (p. 179). "During fifteen years of medical mission work on the coast of North Newfoundland and Labrador, I have discovered that one out of every three or four deaths on the coast is due to tuberculosis" (pp. 256-257).

2. It is impossible to outline adequately the treatment for leukoplakia in a patient one has not seen. In general, it is recommended that the teeth be examined and cared for by a competent dentist; that abstinence from tobacco and similar irritants be enforced; that complicating conditions, such as syphilis, receive appropriate attention. In the early stages of the disease, mild astringents and alkaline mouth washes are employed. In long standing and advanced cases, caustics, such as 20 per cent. chromic acid; freezing with carbon dioxide snow, roentgen ray and radium are utilized. The condition is one best treated by a competent dermatologist.

ORGANIZATION AND CONDUCT OF HOSPITAL FOR DIAGNOSTIC PURPOSES

To the Editor:—Can you tell me if there is a publication which gives, in outline, how to organize, finance and conduct a small hospital for diagnostic purposes? Kindly advise me as to where such information could be secured.

RALPH GETELMAN, M.D., Philadelphia.

ANSWER.—A brief article describing an institution especially designed for this purpose appears under Medical Education, Registration and Hospital Service, in the adjoining column. See also:

COMING EXAMINATIONS

ARKANSAS: Little Rock, May 11-12. Sec. Regular Bd., Dr. I. J. Stout, Brinkley. Sec. Eclectic Bd., Dr. C. E. Laws, Fort Smith.

GEORGIA: Atlanta, June 9-11. Sec., Dr. C. T. Nolan, Marietta.

HAWAII: Honolulu, May 10-14. Sec., Dr. R. W. Benz, 1141 Alakea St., Honolulu.

ILLINOIS: Chicago, June 14-17. Director, Mr. Francis W. Shepardon, Springfield.

LOUISIANA: New Orleans, June 10-12. Sec., Dr. E. W. Mahler, 141 Elk Place, New Orleans.

LOUISIANA: New Orleans, May 4. Sec., Homeo. Bd., Dr. F. H. Hardestein, 702 Machesa Bldg., New Orleans.

MICHIGAN: Ann Arbor, June 8-10. Sec., Dr. B. D. Harrison, 504 Washington Arcade, Detroit.

NATIONAL BOARD OF MEDICAL EXAMINERS: Philadelphia, May 19-26. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia.

NEBRASKA: Lincoln, June 9-11. Sec., Department of Public Welfare, Mr. H. H. Antles, Lincoln.

NEVADA: Carson City, May 3. Sec., Dr. Simeon L. Lee, Carson City.

NEW YORK: New York, Albany, Syracuse, Buffalo, May 18-21. Assistant, professional examinations, Mr. Herbert J. Hamilton, Education Bldg., Albany.

TENNESSEE: Memphis, Nashville and Knoxville, June 11-12. Sec., Dr. A. B. DeLoach, 1001 Exchange Bldg., Memphis.

WYOMING: Cheyenne, June 7-9. Sec., Dr. J. D. Shingle, Cheyenne.

A CLINIC BUILDING FOR THE PRACTICE OF GROUP MEDICINE

E. L. MYERS, M.D., N. M. WHITEHILL, M.D., AND
B. T. WHITAKER, M.D.

BOONE, IOWA

This clinic building has been designed and built for the use of three physicians in order to secure the advantages of

Fig. 1.—Front elevation of clinic building for practice of group medicine.

economy and efficiency that come with the grouping of several practices in a single plant. The building is a face brick and Bedford stone structure, 40 by 72 feet, one story, although built on a foundation sufficient to carry two or more stories. It stands on a prominent corner lot 40 by 100 feet, 28 feet of which is used for a garage for three cars. The building, including the garage, is heated from the central heating plant of the city. An open court at the rear is used for ambulance emergency cases, as it is easily accessible to the roentgen-ray department. Intercommunicating telephone and signal call light systems are used.

The general arrangement is fairly well described by the accompanying illustration of the floor plan. The reception room, 15 by 24 feet, opens just off the front vestibule, and on the opposite side is the library, which at times is used for the overflow from the reception room. The corridor leading from the reception room to the offices of the three physicians has a floor covered with carpet. The vestibule floor is of hand made flemish tile. Each physician has a private suite of two rooms, fitted to suit his peculiar needs, consisting of a consulting room and a treatment, examination or operating room. The latter is finished in white enamel,

having tile floors and hospital metal furniture. The interior is finished in Circassian walnut, except the work rooms and laboratories, which are enameled. A rest room is provided for women, children and those who have to wait long for treatments, roentgen-ray or laboratory tests, etc. The laboratory is completely furnished for chemical, bacteriologic and microscopic work, and is in charge of an expert technician. In the roentgen-ray department the latest equipment, both for treatment and diagnosis, has been installed. The transformer room and developing room are lined with lead. Complete physical therapy equipment has been installed for the treatment

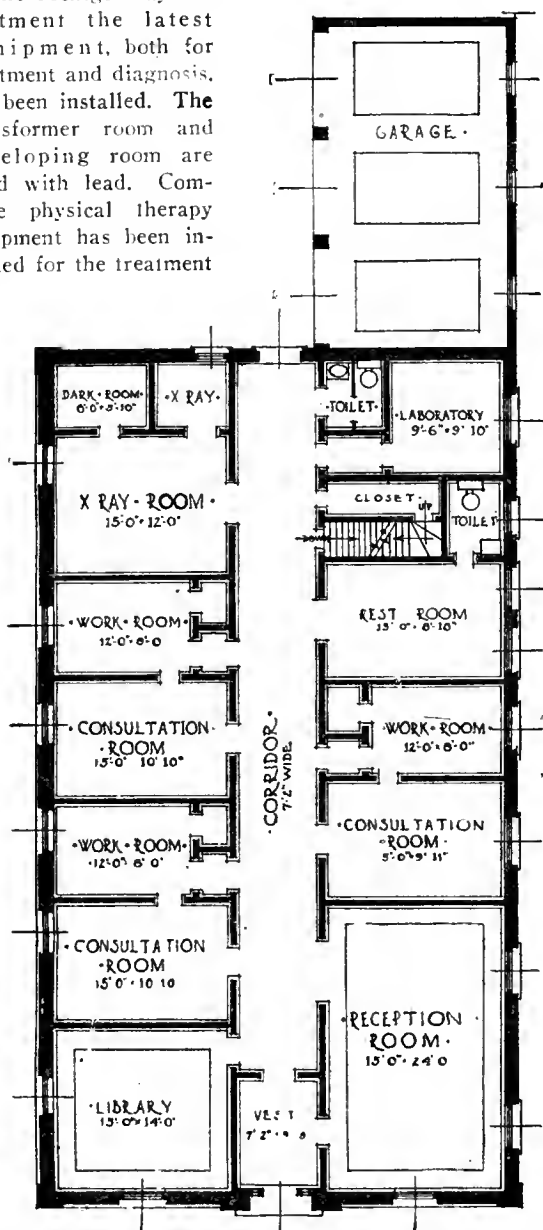

Fig. 2.—First floor plan, 40 by 72 feet, including garage.

of skin diseases, joint and muscular conditions, tuberculosis, neurasthenia etc. The building was erected in 1919 at a cost of \$25,000, including interior light fixtures, decorating, heating, plumbing and electric wiring.

The medical and surgical work will be handled as specialties, and as the work increases, plans will be carried out for enlarging the building by extending the first floor or adding a second story. The business of the organization is carried on through the main office by a salaried manager. The building and equipment are owned and controlled by a corporation, while the business is carried on as a partnership, the running expenses being paid out of a common fund and the members of the partnership sharing in the net income.

The results so far have more than justified this radical move from the generally accepted methods of practice; and if the proper organization can be effected, with men selected for their peculiar fitness, with energy, enthusiasm and consideration for all members of the organization, and free from dissensions and jealousies, the plan is bound to grow as it means better service and greater efficiency. If our short experience is any criterion, we are very optimistic regarding the future of this plan.

Alabama January Report

Dr. Samuel W. Welch, chairman of the Alabama State Board of Medical Examiners, reports the written examination held at Montgomery, Jan. 13, 1920. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Six candidates were examined, all of whom passed. Five candidates were licensed by reciprocity. One candidate was licensed on Army credentials. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Birmingham Medical College	(1914)	80.2
University of Oklahoma	(1915)	81.6
University of Pennsylvania	(1908)	88.3
Memphis Hospital Medical College	(1913)	79
Vanderbilt University	(1919)	84.6, 86.5

College	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Chicago Medical College	(1881)	Wisconsin
Tulane University	(1918)	Louisiana
Omaha Medical College	(1890)	Illinois
Vanderbilt University	(1917)	Tennessee
University of Texas	(1911)	Texas

College	ENDORSEMENT OF CREDENTIALS	Year Grad.	Endorsement with
University of Virginia	(1912)	U. S. Army

Dr. Welch also reports that one candidate, a graduate of the University of the South in 1906, received a license to practice medicine, March 10, 1920, through reciprocity with Louisiana.

Arizona January Report

Dr. Ancil Martin, secretary of the Arizona Board of Medical Examiners, reports the written examination held at Phoenix, Jan. 6-7, 1920. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 16 candidates examined, 11 passed and 5 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
College of Physicians and Surgeons, Los Angeles	(1916)	86.3
Rush Medical College	(1903)	92.4, (1912) 86.9
Kansas Medical College	(1910)	84.1
Washington University	(1910)	83.3
University of Buffalo	(1918)	81.6, 83.4
Jefferson Medical College	(1900)	98.9, (1909) 90.2
Vanderbilt University	(1917)	76
University of Virginia	(1895)	88.5

College	FAILED	Year Grad.	Per Cent.
University of Louisville	(1893)	83.1
Baltimore Medical College	(1904)	81.4
American Medical College	(1892)	71.6
Eclectic Medical University, Kansas City	(1918)	54.9
St. Louis Medical College	(1885)	70.8

Hawaii January Report

Dr. J. R. Judd, secretary of the Hawaii Board of Medical Examiners, reports the written examination held at Honolulu, Jan. 13-15, 1920. The examination covered 8 subjects and included 64 questions. An average of 75 per cent. was required to pass. Of the 11 candidates examined, 5 passed and 6 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Johns Hopkins University	(1915)	88
Cornell University	(1916)	82
University of Pennsylvania	(1913)	85, (1919) 78
Tokyo Imperial University	(1916)	75

College	FAILED	Year Grad.	Per Cent.
Bennett College of Eclectic Medicine and Surgery	(1858)	67
Detroit Homeopathic College	(1909)	67
Nagasaki Special Medical School	(1906)	69
Osaka Prefecture Higher Medical School	(1907)	68, (1914) 57
Tokyo Charity Hospital Special Medical School	(1915)	68

Social Medicine and Medical Economics

THE HEALTH PROBLEMS OF A SMALL CITY

C. H. MAYO, M.D.
ROCHESTER, MINN.

Serving the community as health officer has long, but mistakenly, been looked on as a lowly and trouble-making occupation. When the constitution of the United States was written, general public health problems were not recognized. In order to make the constitution acceptable to a people who had left Europe because of a desire for freedom, the personal liberty and privilege of the individual was made as unrestricted as possible. As the states developed, health problems increased but, from lack of knowledge of both conditions and methods, were relatively few until a recent period. The city charter was usually drawn for the appointment of a health officer by the council at a salary of \$150 a year. The health work was seldom well looked after, as the position was usually a political one, the appointee being too busy or not adapted to the work. The average salary of state health officials is only \$4,000 or \$5,000 a year, inadequate to be sure, but the fault has been with the profession. The city attorney was more important and better paid.

For several weeks in 1908, Rochester suffered from a continued epidemic of scarlet fever. I called a public meeting to discuss the problem and pointed out that the city was getting a bad name for its failure to control contagious disease, and that farmers feared to come to town to trade; this appealed to the business men. The council chamber was stormed, and the health officer resigned; I was asked to accept the position the same evening, and accepted the appointment. The council granted \$2,000 a year for an expense account; there was also several hundred dollars a year income from fees. I appointed a deputy health officer, half time, at \$1,500 a year, and an assistant inspector, half time, at \$50 a month, also a clerk at \$50 a month; and I donated the office, light and heat.

I was later elected to the city school board, a most harmonious and progressive group of individuals, its president a woman. Since then we have sold and rebuilt all but one of the city schools, and have built a high school covering a city block, as well as six fire-proof buildings, housing in all more than 2,000 children. In the high school commercial courses are given, as well as manual and vocational training; there are classes in cooking, dressmaking and housekeeping for the girls. Here also we have a great swimming tank with a gymnasium for the girls and one for the boys, with a physical director for each group; an attractive and instructive moving picture exhibit is given usually twice a week. There is a large school band and orchestra. Military training and drill have been given for the last three years (not compulsory), with most of the older boys in uniform. Here we give the first two years of the regular university course under state supervision at one seventh of the expense at which it can be obtained by nonresidents at the state university. This results in about four times as many of our students securing advanced education as those in other places, and these boys and girls are more mature when they leave home to complete the course at the university amid city surroundings. We have a school nurse who keeps watchful care of absentees. If there is sickness among the children of the poor, the health officer is notified either by the school nurse or the city nurse, the latter being supported by the civic league. The state conducts a school for the care and education of backward children at a cost to the state of several hundred dollars a year for each child; it will allow \$100 a year for each child for the education of these children in their home city. Few such children receive any education, as their parents keep them at home. The local

school board, on investigation, gathered in sixty-six such children, and bought an automobile for the school nurse, who calls for several of these children who could not otherwise attend school. We conduct four such so-called "opportunity rooms" with practically no expense to the city. We are now developing a baby clinic and child welfare clinic with a special nurse and rotating medical service, all under the supervision of the health office. It is hoped that this will give the health officer a full and continuous record of all the children in the city.

It may be asked, Why speak of this school work? From the health office standpoint our greatest trouble in the control of disease comes from the great mass of un-Americans who resist health control of contagious disease as an affront to their personal liberty. This is also true of those who are naturalized, and we have 14,000,000 unnaturalized foreign population, of whom 7,000,000 cannot speak English. By this practical instruction of the children in health work, and by following up the instruction, we secure results which will make these children demand public health protection in the future for their children, as their right while receiving education. In the fall, when school opens, the health officer secures, on request, the services of several physicians of the city, and a complete record is made of each child's general condition on entering school; this examination is of appearance, weight, eyes, ears, throat and physical condition. All previous diseases are recorded on the card, and each year it is added to as the physical health record during school life. The city dentists donate their services, and have established a dental clinic at the high school. All poor children receive free treatment for throat troubles, and free glass fitting.

Inspection of dairy cows and barns is very essential to control bovine tuberculosis and to prevent milk-borne disease. Small cities are denied this protection, although it is shown in many sections of our country that from one eighth to one fourth of the milch cows slaughtered are tuberculous. After two years of effort, mostly educational, with the public and the council, we secured the passage of an ordinance to compel the tuberculin test, with stable and milk production inspection and bacterial tests. The mayor promptly vetoed the ordinance and so we called a public meeting; this time I wished the women to be present, as the mother will fight for the best health interests of the child; the father, a business man, is afraid he will antagonize a customer or a possible one if he takes a pronounced stand in new or progressive movements to which there is opposition. The influence of this meeting justified the council in passing the ordinance over the mayor's veto.

A city veterinarian was then appointed. The next step was to secure the passage of a garbage ordinance under the control of the health office. I then secured a small farm of 30 acres, 2 miles from the city, equipped it and started a hog-feeding farm, and constructed hog houses, waterworks and concrete feeding platforms. I built two small houses and barns for the collectors, and purchased an auto truck, horses and collecting wagons. The garbage is collected from all parts of the city three times a week; a charge of 10 cents a week is made to residences, but there is no charge to hotels. Hogs are purchased weighing from 60 to 80 pounds, double treated with vaccine and serum for cholera, and sold when they weigh from 225 to 300 pounds. During the last year the place has paid for itself, and I presented the outfit together with more than \$2,000 accumulated funds and \$5,000 worth of hogs to the city of Rochester for the use of and to be under the control of the city health department. During 1919, hogs costing \$14,100 were purchased and sold for \$29,200. In this manner the health department is financially aided.

The development of the plan has been of fascinating interest to me.

Book Notices

THE DISEASES OF INFANTS AND CHILDREN. By J. P. Crozer Griffith, M.D., Ph.D., Professor of Pediatrics in the University of Pennsylvania. Two volumes. Cloth. Price, \$16 net. Philadelphia: W. B. Saunders Company, 1919.

The author has presented a review of the diseases of infants and children that is well-nigh encyclopedic. He has consulted a vast amount of medical literature, periodicals and textbooks, and discusses the whole subject in a systematic manner.

He first describes the development of the fetus, and then considers the hygiene of infancy, devoting considerable space to amusements, training, sleep, exercise and other factors in infant disturbances—simple factors that are too often overlooked in the search for obscure causes. The section on sleep is interesting, although the author seems to have overlooked a recent analysis by Strauch which has special reference to psychic factors. The section on breast-feeding is complete, and presents many practical suggestions. In discussing artificial feeding in the first year, Griffith points out the essential features of the two methods known as percentage feeding and the caloric method. He shows that the caloric method is, in the nature of things, an impossibility, without a knowledge of the percentage composition of the milk mixture. In his description of calculations for preparation of correct milk mixtures, the author again presents the card first published in *THE JOURNAL* in 1918, which is an excellent ready reference for easy calculation.

The fifth chapter concerns foods other than milk, and the sixth, proprietary and special named mixtures. "The proprietary foods," the author says, "are unreliable and unnecessary: unreliable, because they are never the perfect substitute for mothers' milk, in spite of the claims of the manufacturers; unnecessary, because it is rare that they cannot be entirely dispensed with." Diet after the first year and diet in sickness are considered, after which the author takes up the characteristic diseases in infancy and in childhood. In the latter section he gives an excellent outline as to the methods of examination and diagnosis, the significance of individual symptoms, a brief discussion of infant mortality, and a general discussion of therapeutics as especially applied in infancy. This concludes the first division of the book.

The second division takes up the diseases of infancy and is divided into twelve sections, in which are discussed diseases of the various body systems—circulatory, respiratory, etc. In this discussion the author shows familiarity with current American and foreign periodical literature and gives due credit for phrases or facts which are borrowed. The treatment recommended is usually rational and simple. The author makes no mention under either measles or scarlet fever of attempts at the use of convalescent serum, although this subject has received considerable attention in recent literature. In the treatment of whooping cough, he is not convinced that vaccines have any value, but believes their use, both as prophylactic and curative is relatively harmless, and may be tried experimentally. In his discussion of the etiology of mumps, he gives many references to foreign literature, but has overlooked some important American investigations: Tunncliffe et al.

In the discussion of poliomyelitis, the after-treatment of the paralyses seems somewhat meager. The extensive studies of Lovett and others of the Boston school deserve mention. Infantile scurvy receives notable attention, but in this case, references to much work done since 1914 are missing and constitute a serious oversight. In this part of the book, pages 610 and 611, several typographic errors are noted. A special chapter is devoted to the diatheses. The author points out that the old view as to the diatheses was succeeded by a tendency to believe that such peculiar systematic reactions do not exist, but that recently it has been found that the diatheses do, in fact, exist. He classifies the diatheses as a "constitutional peculiarity which acts as a predisposition." Special attention is given to the spasmophilic,

lymphatic, neuropathic and exudative types. In the discussion of digestive disturbances, there are colored plates of the types of infant stools, which are instructive.

These volumes will be found especially helpful by the general practitioner who is confronted with children's practice. A well-arranged and fully detailed index to each volume and a general index will enable him to turn quickly to practical discussions of many difficult problems. The books are well printed and beautifully illustrated. There are more than 400 excellent half-tones and twenty fine colored plates.

A PRACTICAL TREATISE ON OPHTHALMOLOGY. By L. Webster Fox, M.D., LL.D., Professor of Ophthalmology, Medico-Chirurgical College Graduate School. Cloth. Price, \$8. Pp. 831 with 306 illustrations. New York: D. Appleton and Company, 1920.

In the new edition of his admirable treatise the author has not only eliminated all ambiguous expressions that may have accidentally appeared in his former work, but also, by incorporating new symptoms, new points of diagnosis and new methods of treatment, has brought it strictly up to date. An especially noteworthy feature of the book is an appendix containing surgical operations, observations on military ophthalmology, and a very large formulary. To all who recognize Dr. Fox's skill as an operator, the technic of his own operation for the relief of conical cornea is of special interest. The operation of excision of the tarsal cartilage in trachoma, which has been ignored in most textbooks, is fully described. The chapters dealing with the various ocular manifestations in constitutional and nervous diseases, subjects passed over very superficially in many textbooks, are discussed in detail. The profusion of illustrations, the happy selection of subjects for the colored plates, and the general typographic excellence of the book will undoubtedly assure the author of a most hearty reception by his professional colleagues.

ARITHMETIC OF PHARMACY. By A. B. Stevens, Ph.D., Ph.C., College of Pharmacy, University of Michigan. Fourth edition. Cloth. Price, \$1.50 net. Pp. 100. New York: D. Van Nostrand Company, 1920.

This practical little book well covers the field expressed by its title. The mathematics of pharmacy is complicated by the necessity of changing from metric to apothecaries' measure and vice versa; by the fact that there are three kinds of thermometers used for measuring heat, and by the custom of writing formulas for solutions by percentages of the various ingredients. The methods and figures given in Stevens' book will save considerable time for those finding such calculations necessary. Each department is followed by suggestive problems, and their solution will be a valuable exercise for pharmaceutical and medical students, as well as for physicians.

COMMON DISEASES OF THE SKIN WITH NOTES ON DIAGNOSIS AND TREATMENT. By G. Gordon Campbell, B.Sc., M.D., C.M., Lecturer on Dermatology and Pediatrics, McGill University. Cloth. Price, \$4. Pp. 229, with illustrations. New York, the Macmillan Company, 1920.

This gives in alphabetical order the commoner diseases of the skin. Fully half the book is taken up with halftones made from photographs which are reasonably good. The text contains nothing but a very short description of the symptoms and a similarly short outline of treatment. With the greatest desire to be indulgent to it, no reason can be found by the reviewer for the publication of such a book, in the face of the existence of a number of really excellent elementary books on skin diseases.

MODERN SURGERY: GENERAL AND OPERATIVE. By John Chalmers DaCosta, M.D., LL.D., F.A.C.S., Samuel D. Gross Professor of Surgery, Jefferson Medical College, Philadelphia. Eighth edition. Cloth. Price, \$8 net. Pp. 1697, with 1177 illustrations. Philadelphia: W. B. Saunders Company, 1919.

This book—a standard work which has made itself a place in American surgery—is now in its eighth edition. The author indicates that the book does not include all of the work done during the war, for sufficient time has not elapsed to place a just estimate on such work. The book is, however, complete and up to date, and is well illustrated.

Medicolegal

Liability for Typhoid Fever Contracted on Boat

(Chicago, D. & G. B. Transit Co. v. Moore et al. (U. S.), 259 Fed. R. 490)

The United States Circuit Court of Appeals, Sixth Circuit, in affirming decrees in favor of eight out of eleven libelants who sought damages for illnesses alleged to have been contracted on a steamer from Detroit, says that it has no difficulty in affirming the conclusion that contaminated water was, during several hours at least, and through the steamer's negligence, provided for the passengers on board. The boat ran aground in Hay Lake, a broadening out of St. Mary's River, about 12 miles below the Soo, and was not released for about six hours, her sea cocks, from which water was supplied to the boat, being embedded in the mud. When she was released, water was pumped from the river into the fresh-water system, without being sterilized or even filtered, and without any attempt to get rid of the mud in the sea cocks except by blowing out with steam. The record indicated that the water of the river at the point from which the water in question was taken was unfit for human consumption; and the boat's officers recognized this, and did not themselves drink it, nor allow the crew to drink it, the faucet ordinarily available to the crew being wired up. Nor was the water served on the table. But neither the faucets in the staterooms nor the fountains in the saloon were sealed, nor was any notice given to passengers that the water obtainable therefrom was not wholesome. In this the steamer was clearly negligent; for it could not be assumed that passengers would refuse to drink the water merely because it was roily.

As opposed to these and kindred considerations were the facts that the water in question was not shown by actual analysis to have contained the typhoid germ; that other methods of infection, as by flies, milk and otherwise, were possible; and that the possibility of infection by other means than the water in question was not conclusively negated. In fact, it must be conceded that the existence of the typhoid germ in the water taken from the river, and served on board the boat, was not proved beyond all possible doubt. But such degree of proof was not necessary. A preponderance of the evidence, a showing of greater probability, was all that was required, and in this court's opinion the evidence preponderated in favor of the final conclusion of the court below. Indeed, there were several features which, taken together, persuasively pointed to that conclusion, including (a) the fact that so large a number of typhoid cases was shown to have developed on the boat; and (b) that, so far as appeared, there were no typhoid cases among the passengers on a sister ship which passed over the course at approximately the same time, but which did not take water from the river.

Each of seven of the libelants having been attended throughout his illness by a reputable local physician, and in each case the disease having been pronounced unquestionably typhoid or of that nature, and treatment given accordingly, this court must reject the contention that the testimony of these physicians was unreliable because based only on clinical symptoms. The most that the court would be justified in concluding here is that, in the absence of confirmation by laboratory tests, a clinical diagnosis of typhoid fever is not absolutely conclusive. But the results of evidence in cases of this nature do not require absolute scientific certainty, and the court thinks the testimony of the attending physicians established, by a fair preponderance of the evidence, the existence of typhoid or similar fevers. That in the case of each of several of the libelants, expert medical witnesses of high standing expressed the opinion that, on the hypotheses contained in the question submitted to them, the patient was not suffering from typhoid fever, at most raised only a question of fact.

The court also thinks that there was sufficient evidence in the case that one of the libelants contracted arthritis as a result of drinking the impure water, and that in another

passenger an attack of gallstones was the direct and immediate result of typhoid fever caused by drinking the water.

An award of \$1,500 damages as actual compensation for pain and suffering from typhoid fever, the court holds cannot be considered excessive; and in addition to that, it approves of various allowances for loss of time and services to business, while, in the gallstone case, in addition to the allowance for pain and suffering from typhoid fever, \$2,000 for past and future suffering on account of the gallstone trouble, as well as \$1,545.69 for medical expenses incident to the typhoid fever and gallstone trouble combined, are approved.

Chiropractor as Assistant to Regular Physician

(State v. Young (Mo.), 215 S. W. R. 499)

The St. Louis Court of Appeals says that the defendant, who was charged with practicing medicine without a license from the state board of health, admitted that he was a chiropractor, but contended that he was engaged as an assistant to a regularly licensed physician, and offered evidence to that effect, which was excluded. But such exclusion was not error, as the defendant could not escape the effect of the statute by showing that in practicing his profession he was employed by another and acted under another's direction. Under the law of Missouri, one engaged in chiropractic is practicing medicine. However, the judgment of conviction in this case was reversed, and the cause remanded, because the verdict being general in character was bad, in view of the fact that the information charged separate and distinct offenses, namely, practicing medicine, attempting to practice medicine, and advertising as a physician, without a license. The verdict should have been specific as to whether he was guilty of one or the other of the offenses, or of all of them. As it was, some of the jury may have believed him guilty of one of the offenses, and some of another, while he was entitled to have twelve men believe him guilty of either one or all of the stated violations of the statute.

Physical Signs of Foreign Bodies in Bronchi.—Decreased expansion on the affected side, the presence of very fine râles and the "asthmatoïd wheeze," McCrae regards as signs of value in the diagnosis of foreign body in a bronchus. Some foreign bodies, such as a peanut, set up a very acute general process which is fairly distinctive. Other structures, such as metallic objects, cause permanent changes, usually in a lower lobe. The chief errors in diagnosis are to mistake the signs for those of pneumonia in the early stages and in the acute cases, and for tuberculosis after the body has been present for some time.

Oculopupillary Fibers of Sympathetic System.—The conclusion is formulated by Spiller that in man the oculopupillary fibers do not decussate, or at least in very slight degree, in the pons or below this in the medulla oblongata or cervical cord. In two cases of tubercle of the pons, which is a lesion destroying the axis cylinders where it exists and not permitting them to pass through as does glioma, the oculopupillary symptoms were on the side of the lesion. Spiller has repeatedly seen oculopupillary paralysis of the sympathetic on the side of the lesion resulting from occlusion of the posterior inferior cerebellar artery. This occlusion produces softening in the lateral part of the medulla oblongata. Spiller admits the possibility that the sympathetic fibers may decussate in the cerebral peduncle, but says the evidence of this is far from conclusive.

Encephalitis.—In the experience of Barker and others a cell count in the cerebrospinal fluid of from ten to 100 small mononuclears, along with a positive globulin reaction, with negative Wassermann and negative bacteriologic smears and cultures, is, at the time of an epidemic of encephalitis, strong corroborative evidence of the existence of the disease in a patient in whom the process is for any other reason suspected to exist. Negative findings in the cerebrospinal fluid do not, however, rule out the disease. The clinical course of the disease is discussed and eight cases are analyzed. A very fine list of selected references is given, including papers of importance as earlier sources of conception of nonsuppurative encephalitic syndromes; papers on nonsuppurative encephalitis by American authors (before the present epidemic); papers on the pathologic anatomy and histology of nonsuppurative encephalitis; papers on the recent epidemic of nonsuppurative encephalitis North American, South

America, Great Britain, France, Oceanica (Australia), Austria, Germany and Africa.

Pleural Effusion with Inversion of Diaphragm Producing an Abdominal Tumor.—On the occasion of a necropsy, Riesman found in the left upper abdominal quadrant a large, smooth, tense tumor, which on further exploration, proved to be a bag made by the inverted diaphragm and filled with pleural fluid. Since then he has seen this tumor twice, clinically. The condition is a mechanical result of great intrapleural pressure.

Retroperitoneal Liposarcoma.—Hirsch and Wells report the microscopic and chemical examination of a retroperitoneal liposarcoma without myxomatous elements, weighing 69 pounds, being the largest solid tumor on record. It illustrates the capacity of malignant tumors to store up protein and fat, despite extreme emaciation of the host.

Evidences of Nephritis and Urinary Acidosis.—The observation made by Barach show that in the most severe type of exertion (Marathon race), albumin and casts and red blood cells occur in all individuals. The casts were of the broad and narrow, hyalin and granular variety. Some of the casts showed red and white corpuscles. The amount of albumin was greatest in those who ran strenuously, finishing earliest, from three hours and fourteen minutes to four hours and fifteen minutes. Observations of the blood pressure and pulse rate in these cases showed that the largest amount of albumin and blood and casts occurred in those individuals who showed the greatest degree of circulatory disturbance. This was manifested by a marked fall in both the maximum blood pressure and in the pulse pressure. In the less strenuous type of exertion are usually found an increased urinary acidity, albuminuria, cylindruria and, at times, blood cells. A critical analysis of these findings, however, shows, first of all, that in the more strenuous effort the amount of albumin, the presence of blood cells and the number and type of casts all depict a more serious renal disturbance than is found in the less strenuous form of exercise. Urinary acidity was increased after exercise in 85 per cent. of the cases, but it did not occur more frequently, nor was the acidity higher in the severe exertion cases than in the milder ones. There is a positive relationship between the degree of albuminuria and cylindruria and the type of physical exertion; but these observations show that no such relationship can be established between the urinary acidity and the occurrence of albumin, casts and blood cells in the urine.

Association of Fever with Fracture of Skull.—Fever occurred in fifteen of a series of seventy-two cases of fracture of the skull recently studied by Wilensky. In another series of cases of fracture of the skull admitted to the hospital in a different period of time, twenty-two patients of a total of seventy-seven developed fever. In the fifteen febrile cases of the first series the fractures were situated in the posterior fossa in six cases and in the middle fossa in two cases; in the others the fractures were distributed over the vertex and sides of the skull. One fracture was compound externally; one communicated with the middle ear and two fractures with the nasal cavities; the others were all closed fractures. Eight of the patients who developed fever died; in four of these the cause of death was a meningitis.

Pathology of Influenzal Pneumonia in France.—One hundred and six necropsies are analyzed by Bakwin. Changes in the rectus muscle were observed in 33 per cent. of the cases. Empyema was rare, occurring in less than 4 per cent. of the cases. Acute laryngitis was comparatively rare, occurring in only six out of thirty-eight larynges examined (16 per cent.). Sphenoid sinusitis was a very common complication and was found in twenty out of twenty-two cases examined (90 per cent.). Seven out of thirty-five autemortem blood cultures showed pneumococci. The rest were sterile, with the exception of one, which showed a meningococcus. The bacteria found in the organs at necropsy were varied; *Streptococcus hemolyticus*, the pneumococcus, staphylococcus, nonhemolytic streptococcus, *B. influenzae* and gram-negative cocci being found in the various cases in the order of frequency given above.

Cause of Epilepsy.—Marsh is of the opinion that epilepsy is an abnormal muscular reaction to strong mental states. It is an abnormal expression because such muscular activity does not gain the end for which the emotional state was generated. It is unnatural, also, since it is effort undirected. The epileptic, because of his peculiar make-up cannot avoid the dangers of too great stress as the normal man meets it, but by an emotional drive that cannot be readily checked, labors on to mental exhaustion in unconsciousness. This is not deep enough to involve the motor of life centers of the brain, so a convulsion takes place. Viewing epilepsy in this light, it is now possible, in treating this disorder, to institute more rational methods than has previously been had in surgical procedure and in empirical therapy.

Arthritis.—Of four hundred cases of arthritis studied by Pemberton and Robertson, it was found that 256 patients had arthritis only; 112 had a combination of arthritis and myositis; twenty-two had myositis only; seven had nerve involvement (neuritis) only, and three were listed as doubtful. One hundred and seven persons were taken sick in the apparent absence of demonstrable surgical foci. Two hundred and ninety-three persons showed demonstrable surgical foci. Of this latter number 208 showed foci in the tonsils. One hundred and thirty-four persons in the entire series were positive for a genito-urinary focus. Seventy-eight showed a combination of both dental and tonsillar foci. It was also found that thirty-eight persons showed some combination of foci other than dental and tonsillar, as for instance dental and genito-urinary or tonsillar and genito-urinary.

Basal Metabolism in Arthritis.—Of the twenty-nine cases studied by Pemberton and Tompkins, 80 per cent. showed a metabolism within normal limits; 20 per cent. showed a metabolism slightly below normal limits. The metabolic data give no explanation for this deviation. From the respiratory quotients no abnormality can be detected in the percentage of calories obtained from the three foodstuffs. Nothing abnormal was found in the pulse, temperature or minute volumes of air breathed at the times of the determinations. In the cases showing a basal metabolism below the normal limits, no particular relation could be determined between the severity of the disease, age or condition of the patient (whether active or bed-ridden), atrophy of muscle, edema or other factors.

Studies on Nitrogen, Urea, Etc., in Arthritis.—In a series of sixty-seven observations in fifty-seven cases of chronic arthritis, the fasting blood nitrogen fell within normal limits in all but two cases. One of these patients had cirrhosis of the liver and renal calculus. He gave 45.4 mg. of nitrogen per hundred c.c. of blood. The other patient had a chronic arthritis of one knee. He gave 38.5 mg. The carbon dioxid combining power of the blood in seventeen cases of chronic arthritis fell well within normal limits. The same was true of the calcium of the circulating blood, and the total fat and cholesterol of the fasting blood. The authors go into considerable detail in their discussion of a definite relation between the intake of food on the one hand, and the inci-

dence or perpetuation of symptoms of the disease on the other in cases of chronic arthritis. This relation is best illustrated by the fact that the institution of a reduced diet in appropriate cases may be followed by marked benefit. Of the three foodstuffs, the evidence at hand, although not yet complete, has indicated that carbohydrate is most concerned in this connection. Studies were carried out in sixty cases of arthritis on the fasting level of the blood sugar and on the response of these cases to the so-called glucose tolerance test. The results are given in full. Experience suggests that the sugar tolerance test may sometimes be helpful to indicate whether all foci of infection have been removed. The disturbance of the sugar tolerance due to focal infection, apparently accompanies the failure of the organism successfully to maintain its wall of defense and is apparently restored to normal when this defense returns. In this light a lowered tolerance, following on a focus, becomes an intermediary, or, at least, a concomitant step in the pathology of arthritis and possibly other conditions as well.

Analyzing Electrocardiogram.—A new method is presented by Mann in which the ordinary three leads of the electrocardiogram are combined in a single curve, the mono-cardiogram. The usefulness of this method of analyzing the electrocardiogram is explained.

Irritation of Vagus and Stomach Erosions.—All of Nicolaysen's experimental observations were made on animals. Ten cases in human beings were observed clinically. In the first group of six cases, irritation of the vagus was produced during the course of the illness which in every case was situated in the brain or its membranes. In the second group of three cases the disease involved the chest, the lungs and pleura being the seat of infiltrating processes. In a case of cancer of the breast with metastases in the lung and pleura there was infiltration of the vagus and symptoms of vagus paralysis. In one case, one of peritonitis with empyema, it is possible that there may have been involvement of the nerves of the stomach in the abdomen as well as in the thorax, although the proof that such was the case cannot be supplied. The vagus nerves and the nerves of the stomach in these ten cases should have been examined microscopically, but the material was gathered originally in the course of a study of ulcer of the stomach; it was only later that Nicolaysen's attention was directed to the hemorrhagic erosions of the stomach in these cases. The results of the study shows that in most of the cases in which hemorrhagic erosions were found, there had been irritation of the vagus or the possibility of such irritation. To conclude from these cases that hemorrhagic erosion always results from irritation of the vagus does not seem warranted, in Nicolaysen's opinion. It is possible, that in some of these cases it concerns a coincidence. However, Benke's results and the pilocarpin experiments in rabbits favor the conclusion that vagus irritation may cause erosions.

Determination of Normal Vital Capacity.—A group of 129 persons were studied by West for the purpose of comparing various standards for determining the normal vital capacity. A standard based on the body surface area is advised, since it has been shown that the vital capacity varies with this function more uniformly than with others tried. When the weight of the patient cannot be obtained, a standard based on the height is recommended.

Platelet Count in Diseases of Blood.—The method of Oluf Thomsen for counting the platelets in citrated plasma is described by Gram. The number of platelets in normal individuals lies between 200,000 and 500,000. The platelets are diminished in number in pernicious anemia, in most cases of lymphatic leukemia and in some cases of myeloid leukemia. Normal values are found in hemophilia, and augmented values are found in many cases of simple anemia and some of myeloid leukemia. The diagnostic and prognostic importance of the platelet count in diseases of the blood is discussed. The bleeding time determination of Duke helps to disclose a latent hemorrhagic diathesis due to platelet deficiency, as symptoms may not appear without a provocative cause. It is shown that platelet counts of less than 100,000 per c.mm. generally cause a tendency to bleed. The counting of the

platelets and determination of the bleeding time is considered by Gram as of extreme importance as a preoperative measure, especially in cases of aplastic anemia, in which an operation often is performed for explorative, occult cancer being suspected.

Influence of Desiccation on Natural Hemolysins and Hemagglutinins.—Kolmer maintains that drying normal human serum on cover glasses and in paper at ordinary room temperatures frequently results in marked or complete deterioration of the normal isohemagglutinins. Deterioration of these normal isohemagglutinins is especially evident within the first to fourth days after the serums have been dried. Similar results were observed with hemagglutinins in normal human serums for the corpuscles of the lower animals. Human serums containing large amounts of normal hemagglutinins when dried under ordinary conditions and properly kept in a refrigerator may prove satisfactory for microscopical tests for at least two weeks, due to the presence of sufficient agglutinins escaping destruction. Only such serums should be used for drying and tests should be made at the end of the first week to determine if agglutinins are present before the cover glasses are used for the typing of bloods. The hemolysins found in normal human serums for the corpuscles of persons and the lower animals also deteriorate on desiccation under ordinary conditions and are somewhat more susceptible than the hemagglutinins. For the grouping of blood, serums should be kept in a fluid state sealed in ampoules at a low temperature, both hemagglutinins and hemolysins in normal human serums being highly susceptible to heat.

Nature of Thermolabile Hemolysins.—The experiments reported on by Kolmer indicate that the natural hemolysins in human serums are distinct substances and not differentiated complements. Natural hemolysins are susceptible to heat being inactivated (masked) or destroyed when serums are heated at 56 C. and totally destroyed by heating at 62 C. The natural hemolysins in human serums vary in resistance to heat, antishoop hemolysin being most resistant (thermostable) and antiginea-pig hemolysin being most susceptible (thermolabile).

Bearing of Intestinal Infection on Pregnancy.—The intestine in the human being swarms with bacteria, notably the colon bacillus. The mechanical conditions prevailing in the abdomen as pregnancy advances are such that interference with the peristalsis of the bowel and the accumulation of fecal matter during pregnancy are inevitable. In addition to this, congestion of the abdominal viscera must be present to some degree during pregnancy in the majority of patients, and a combination of these two conditions, Davis says, furnishes a state of affairs exceedingly favorable for the development of infection of intestinal origin. This may manifest itself most frequently in appendicitis, cholecystitis, infection of the lymphatics of the intestine and peritoneum, or infection of the blood stream. While some patients pass through pregnancy without the use of purgatives and laxatives this is not true of the majority. What is described is to render the fecal mass in the bowels soft and unirritating and to promote peristalsis and to keep the bowel in a tonic condition. In the use of drugs care must be taken that the ganglia in the uterine muscle are not stimulated to contraction by drugs which stimulate peristalsis of the bowel, for excessive uterine peristalsis will cause abortion. That there is danger in the prolonged retention of hard feces in the intestine of the pregnant woman has been demonstrated. What is especially needed to promote intestinal peristalsis in pregnancy is exercise by walking. Where this cannot be procured, calisthenic exercises during pregnancy are of considerable value, and should these be impossible massage by skilful hands may often be employed to great advantage. Exercise, cold bathing followed by gentle rubbing, the plentiful use of fruit, water and cereal foods, and regular and systematic attention to the matter will enable many patients to pass through pregnancy without the use of purgatives. If laxatives are necessary, refined petroleum with compound licorice powder, is often successful. In the presence of toxemia, drugs which act vigorously on the eliminative organs must be used, but without this indication purgation during pregnancy should be avoided.

Observation Hospital for Mental Defectives.—Schlapp urges the erection of a detention hospital where all persons suspected of defectiveness can be examined properly and their condition ascertained. There should be the closest of contact between this hospital and the courts and other public institutions. The proper execution of tests requires periods of fasting, quiet, and observation, which cannot be observed unless the patient is detained. Besides reception and consultation rooms, wards, recreation, and living quarters, such an institution as would meet the requirements must have laboratories fully equipped both for complete tests and research. Every provision should be made for prompt and thorough examination by a staff of specially trained observers and nurses and there should be either a sufficient endowment fund or an assured appropriation in order to prevent embarrassment, or limitation in the scope of work.

Value of Complement Fixation Test for Tuberculosis.—Buddy analyzed this test in thirty-six cases of suspected

tuberculosis. Twenty patients, or 55.5 per cent., gave a positive reaction. There were eight positive Wassermanns and six clinically diagnosed as having syphilis and tuberculosis. Of sixty-nine cases with diagnosis other than tuberculosis, twelve, or 17.3 per cent., gave positive complement fixation tests. Of the sixty-nine cases, one in every 57 cases gave a positive complement fixation reaction and one in every 8.6 cases gave a positive Wassermann. Buddy points out that the complement fixation test for tuberculosis is of some value in the cases of positive tuberculosis. A negative reaction in this class usually indicates far advancement with every grave prognosis. It has a clinical value as additional evidence in clinically active tuberculosis. In suspected cases it has a slight value only in being an additional factor for or against tuberculosis. A diagnosis of clinical tuberculosis cannot be made from a positive reaction, neither can tuberculosis be excluded from negative reaction. It is not of so much value in tuberculosis as the Wassermann reaction is in syphilis. It is an aid only when considered in conjunction with complete history and thorough physical examination.

Id.—Ives maintains that this test can never determine positively whether or not a patient is ill with tuberculosis. On the other hand, the results of the test are in fairly close harmony with the true condition of the patients who have been tested, and hence the test should influence judgment in arriving at a diagnosis. This test should not displace clinical observations, but if properly used it will stimulate the clinician to make more accurate and thorough observations.

Loss of Abdominal Reflex in Abdominal Conditions.—Analysis of a considerable number of cases has convinced Williams that the loss of the abdominal reflexes in abdominal conditions may be regarded as a phenomenon of fatigue of the reflex, this fatigue being caused by a previous stimulation of the reflex by a painful affection in the abdominal area; and it is suggested that the fatigue of the reflex may be cerebral rather than spinal. The local loss of the reflex, e. g., the right lower reflex in appendicitis, or the general loss of all four reflexes of a patient whose abdominal wall is in good condition, is of considerable clinical value; but its value is not absolute, and it must be determined together with the other features which go to make up the picture of the case.

Monobloc's Operative Treatment of Tuberculous Lymphangitis.—Although the treatment of tuberculous lymphangitis by the excision of the primary focus, the affected vessels and the glands of which they are afferents, is recognized as, perhaps, the only effective treatment for tuberculous lymphangitis of the limbs, Handley doubts whether the importance of excising all the affected tissues in one piece has been properly emphasized. Obviously, if the removal is carried out in sections, the chances of a reinfection of the wound are greatly increased. He cites a case of tuberculous lymphangitis following injury to a tuberculous wart of long standing in which the result was not perfect, and the policy of attacking the recurrences, which sometimes gives such satisfactory results in carcinoma, was followed with a considerable degree of success. From the microscopic examination of many specimens, Handley is convinced that lupus vulgaris is essentially and primarily itself a lymphangitis of the cutaneous and subcutaneous lymphatics, and that it differs from "tuberculous lymphangitis" only in its slow and limited spread through the lymphatics. The principal reasons for this belief are: The plane primarily affected, namely, the superficial layer of the dermis, is the plane of origin of the lymphatic vessels of the skin. Changes in the lymphatic vessels of origin can be seen beyond the clinical edge of the area of lupus. Moreover, isolated giant cell systems can often be found in the subcutaneous tissue, showing that this layer also is affected as well as the skin, and these isolated giant cell systems are usually found close to the blood vessels, in the situation of the comitant lymphatics.

End Results in Partial Amputations of Foot.—The conclusion reached by Irwin as the result of an investigation of partial amputations of the foot is, that, unless more of the limb can be saved than that found in Lisfranc's amputation, the function of the limb, as estimated by the man's capacity for work, his ability to keep time, and his value as a unit in the general industrial machine, will be improved by the complete amputation of the foot through the ankle joint after the manner of James Syme.

Bridging Gaps in Injured Nerve Trunks by Autogenous Fascial Tubulization and Autogenous Nerve Grafts.—In the eighteen operations analyzed by Platt in which fascial tubulization combined with autogenous nerve grafts, fascial tubulization alone, and autogenous vein tubulization (one case), were used, there was a complete absence of any sign of recovery. The shortest period over which observations were made was four months, the longest period twenty-six months. Secondary exploration in four cases showed complete silence of the nerve trunk to direct faradic stimulation. End-to-end suture was accomplished in all after excision of the bridged segment. At the re-exploration operations, partial or complete obliteration of the lumen of the fascial tube was noted. In two specimens examined his-

tologically, one, a tubulization alone, showed obliteration of the lumen of the tube by fibrous tissue in which no nerve fibers could be found. In the second, a graft and tubulization combined, nerve fibers were present in the center of the obliterated tubule eighteen months after the operation. There was no sign of continuity between the proximal and distal ends through this strand of nerve fibers. Platt is of the opinion that the early re-exploration of all graft and fascial bridge operations is advisable.

Local Discoloration of Abdominal Wall as a Sign of Acute Pancreatitis.—The case of a woman, aged 54 years, suffering from an acute abdominal illness of three days' duration, is cited by Turner. On the abdominal wall, surrounding the umbilicus, was an area of discoloration about 6 inches in diameter, of a bluish color, very like the postmortem staining seen on the abdominal wall or the appearance of the skin in a late case of extravasation of urine. The area was slightly raised, and pitted on pressure. The patient suffered from acute pancreatitis, with much effusion into the peritoneal cavity. She lived nine days after operation, and the postmortem examination disclosed a sloughing pancreas with much fat necrosis. In another similar case there were two large discolored areas in the loins. They were about the size of the palm of the hand, slightly raised above the surface, and of a dirty greenish color. There was a little edema with pitting on pressure, but there was no pain or tenderness. The urine was full of sugar. A diagnosis of acute pancreatitis was made; and this was confirmed by an immediate operation. Turner says he has never seen mention made of this sign.

Fracture of Atlas Vertebra.—Four cases of fracture of the atlas vertebra are described by Jefferson, and forty-two cases previously recorded in the literature are analyzed. The common cause of the accident is a fall on the head, and the probable mechanism of fracture is tension of the atlas ring due to lateral spreading of the lateral masses, owing to the divergence of the lines of force passing through the bone. Two other possible mechanisms are outlined, the head being in extreme extension, but neither fits in with the nature of the accidents usually recorded. Atlas fracture is by no means necessarily fatal; 45.7 per cent. of the patients have recovered. When complicated by a fracture of another vertebra, the mortality is higher. The commonest of such complications is a fracture of the odontoid process, next in frequency being rotary dislocation of the atlas on the axis. It is pointed out that inability to rotate the head may occur in some forms of atlas fracture. It is not pathognomonic of a broken odontoid. The accident is probably by no means uncommon, but as very clear and sharp roentgenograms are necessary in order that the fracture may be detected, the atlas injury is often overlooked. Cord injury is often absent (50 per cent.). Useful aids in diagnosis may be obtained from signs of injury to the great occipital nerve. Treatment will generally be conservative, directed to immobilizing the head by a "Minerva" plaster or a Lorenz bed.

*Comparative Study of Bruck and Wassermann Reactions. M. Terada.—p. 44.
Action of Adrenin and Various Extracts of Glandular Organs on Veins. Tugane.—p. 51.

Comparison of Bruck and Wassermann Reactions.—Terada made a comparative study of both reactions by using the serum of 150 syphilitic and nonsyphilitic patients whose cases were clinically diagnosed. In the primary stage of syphilis, Wassermann's reaction was positive in seventy-five cases, Bruck's reaction was positive in fifty cases; in the secondary stage (of syphilis), the former was positive in eighty-eight cases and the latter in eighty-five cases. In the tertiary stage, Bruck's reaction was positive in eighty-six cases and the Wassermann in eighty cases. In cases in which the presence of syphilis was very doubtful, the Wassermann reaction was positive in thirty-nine cases and Bruck's reaction was positive in forty cases. Finally, in nonsyphilitic cases, the Wassermann was positive in twelve cases and Bruck's reaction was positive in twenty-five cases. Bruck's reaction always showed a smaller positive percentage than Wassermann's in each stage of syphilis, while Bruck's reaction always indicated a higher positive percentage than Wassermann's in nonsyphilitic cases. Terada recommends Bruck's reaction as an aid in the diagnosis of syphilis when a complicated method, such as Wassermann's reaction, cannot be used. Naturally, however, the decision of a serious question such as the diagnosis of syphilis should never depend on Bruck's reaction alone.

Archives des Mal. du Cœur, etc., Paris

November, 1919, 12, No. 11

*Anemia in Young Children. E. Lenoble.—p. 481.
*Rachitis with Embryonal Bone Marrow. Idem.—p. 488.
*Functional Aortic Insufficiency. J. Bret.—p. 494.
Interpretation of Oscillometer Findings. E. May.—p. 502.

Anemia in Young Children.—Lenoble reports a case of pseudoleukemic anemia, or actual myeloid leukemia with anemia, in a child of 3, the blood picture the reverse of the usual formula in children. He comments that the rôle of hematology and pathologic anatomy has been well studied in anemia but the rôle of parasitology and serology has scarcely begun to be investigated. Another boy of 3 presented hemolytic jaundice of the pernicious anemia type, with intestinal hemorrhages for over a year. The tint was more waxy than jaundice, and the upset in the blood picture suggested

that a parasite or toxin was responsible. There was nothing to suggest syphilis in either case.

Rachitis with Embryonal Bone Marrow.—The infant of 17 months had rachitis and inherited syphilis, but Lenoble exonerates the spirochete from the responsibility for the rachitis, the blood being approximately normal. But the bone marrow of the femur showed what he calls *réviescence embryonnaire*, of the type described by Dominici as latent myeloid reactions. This finding is particularly important in connection with the theory that rachitis is primarily a disease of the bone marrow—a reaction of the bone marrow to chronic infections and intoxications.

Functional Aortic Insufficiency.—Bret's experience with seven cases seems to warn that the Corrigan syndrome without true diastolic hypotension is probably of functional nature. Functional aortic insufficiency may be found in the course of chronic nephritis, associated or not with adherent pericardium. It is a disturbance in the heart action rather frequently observed with high blood pressure. Mechanical factors elsewhere in the aorta may contribute to its production, as he explains.

*Cicatricial Stenosis of the Larynx in Children. E. J. Moure.—p. 59.

*Sarcoma of Kidney. Orasion and Faure.—p. 60.

*Variations in Acidity of Gastric Juice in Vitro. H. Barthe and Malgoyre.—p. 63.

*Colloidal Therapeutics. J. Vergeley.—p. 64.

Cicatricial Stenosis of the Larynx in Children.—Moure refers to conditions left after long wearing of a tracheotomy tube. When the opening for it had been made not in the trachea but through the tissues above, the stenosis can be corrected more easily than where the opening is in the trachea itself. It is better not to attempt the operation on children under 7 or 8 as the passages are so small, and the laryngostomy followed by cleaning out the cavity and consecutive dilation may entail pulmonary complications. If the stenosis is the result merely of a bad position of the tube, correcting its position may cure the stenosis, which is inflammatory rather than cicatricial. Patience is necessary here, watching over the throat to prevent exuberant granulations around the tube, excising them from time to time and cauterizing with the actual cautery or with 1 per cent. zinc chlorid. In time the passage will become permeable, but the tube should never be discarded without ascertaining with the mirror that the vocal organ is freely permeable. The children have to be trained to breathe through the natural passages, by plugging the tube during the day and, later, at night. There is no need to use special tubes for the purpose. Even if the stenosis is from cicatricial tissue inside the larynx, it can only benefit from the above measures, being in better condition for the correcting operation when the child has reached the proper age. In a case described in a boy of 3, the tube had been introduced just below the thyroid, and the opening had filled up with granulations which had to be excised or cauterized every two weeks for over two years. Then the opening gradually healed, and three years after the tracheotomy had been done, the training of the child to breathe through the natural passages was begun. In four months the tube could be discarded, and several months later the tracheal fistula was closed. The boy is now 10 and the larynx and trachea have developed apparently normally.

Sarcoma of the Kidney.—The young man suddenly developed symptoms suggesting right pyelonephritis. Intense anemia and progressive weakness imposed nephrectomy although there was no hematuria and the functioning of the kidney did not seem to be much impaired notwithstanding the sarcomatous degeneration. The patient was too weak to rally. The whole course was less than four months.

Variations in Acidity of Gastric Juice in Vitro.—Barthe and Malgoyre present evidence that the gastric juice increases or loses in acidity on standing. Their findings showed a loss of from 10 to 33 per cent. in three cases the forty-eighth hour, and a gain of from 6 to 20 per cent. in

the others. In one case there was a loss of 25 per cent., but this was made up and surpassed later, the third day showing an increase of 20 per cent. over the findings when the gastric juice was first drawn.

Colloidal Therapeutics.—Vergely here gives a survey of the field of colloids in therapeutics and the experiences to date with these inorganic ferments, metallic ferments or electric colloid metals as they are variously called. Their catalytic action is explained by their enormous surface. A liter of a 0.5 per thousand solution of colloidal gold, for example, presents a surface of 150,000 square centimeters, while the same weight of gold in a compact form presents a surface of only 50 square millimeters. In therapeutics, they whip up the organism but if it is unable to respond, they can do no good. If the patient is unable to produce more leukocytes, if the opsonic index is too low, there is no chance of success. In selecting the colloid to use, he advises the metal that has been found most active against the bacteria, etc., involved. He adds that injection of a colloid may favor the production of a fixation abscess when this is attempted at the same time. There is a place for colloidal therapeutics, he concludes, besides vaccine therapy and serotherapy, but its principal indication is in chronic disease or infection in which a specific chemotherapy is required.

*Roentgen Study of Atony of the Digestive Tract of Nervous Origin. F. Barjon.—p. 109.

*Auto-Experimental Study of Pruritus. P. Jourdanet.—p. 116.

Atony of Digestive Organs.—Barjon emphasizes the importance of atony of the esophagus and stomach in the clinical picture of neurasthenia and other nervous disturbances. The discovery of atony of any segment of the digestive tract sustains the assumption of a nervous origin for the various disturbances noted anywhere in the body. If the symptoms from the atony are accepted as of organic origin and an operation is done, the symptoms continue afterward the same as before. He describes three extreme cases, and warns to seek for atony of the digestive tract before operating in all dubious cases.

Auto-Experimental Study of Pruritus.—Jourdanet remarks that as pruritus is a sign that the nerve terminals are suffering, it belongs to the sphere of the neuropathologist. He has been making a detailed study of it in his own person as he could bring it on at will by taking antipyrin. He is subject to itching eruptions when he takes this drug but never has pruritus at other times. His experience confirms that the pruritus is most severe at points subjected to strain or pressure. Scratching fastens, increases, and generalizes the pruritus, as also sudden exposure to air. He received a telegram announcing a death in the family, and an explosion of generalized pruritus followed immediately on this emotional shock, and persisted for an hour.

*Radiotherapy of Uterine Fibromyomas. A. Bécère.—p. 101; of "Primary" Neuralgia. A. Zimmermann.—p. 105; of Local Tuberculous Processes. P. Cottenot.—p. 107.

*Radium Treatment of Uterine Cancer. Th. Nogier.—p. 111.

*Radium Puncture in Treatment of Cancer. C. Regaud.—p. 118.

*Radium Treatment of Cancer of Esophagus. Dufourmentel.—p. 124.

Radiotherapy of Uterine Fibromyomas.—Bécère credits Foveau de Courmelles with the first application of the roentgen rays in treatment of uterine fibromyomas. His first communication on the subject appeared January, 1904. Bécère's own experiences with over 400 cases compel the assumption that radiotherapy is applicable to every uterine fibroma except where conditions demand surgical intervention at once. He gives weekly exposures, and records the size of the fibroma at each sitting; this testimony demonstrates the primary and direct action of the rays on the fibromas. In three cases the roentgen rays induced the retrogression of uterine fibromas which had developed several years after the natural menopause.

Radiotherapy of Neuralgia.—Zimmern relates that the success of roentgen treatment of neuralgia by raying the roots of the nerves involved has been remarkably constant in all forms of neuralgia except the facial. Sciatica and neuralgia of the brachial plexus have responded especially promptly and completely. Relatively small doses are required; not more than one or two applications of 3 H units notably attenuate the pains or cure them completely. The area exposed for brachial neuralgia should be from the fourth cervical to the first thoracic vertebra. He has made a special study of radiotherapy of neuralgia since 1913, and increasing experience, he says, has confirmed its value.

Radiotherapy of Local Tuberculous Processes.—Cottenot is the radiologist at the Saint Louis Hospital and his experience confirms the beneficial action of roentgen-ray treatment in many cases of tuberculous gland, joint and bone disease. With osteitis and arthritis he prefers to combine it with immobilization, making as many windows in the cast as possible, so that cross-fire raying can be done. In certain other forms of local tuberculosis, curetting followed by raying seems to insure a permanent cure.

Radium Treatment of Uterine Cancers.—Nogier gives illustrations of the different devices he uses in applying radium treatment to the vagina, uterus or rectum to insure a certain space and filtration between the radium and the tissues, and still have the radium in the heart of the tumor, so as to take advantage of all the rays.

Radium Puncture in Treatment of Cancer.—Regaud refers to needles loaded with radium emanations and plunged into the neoplasm. The circles of influence from the radium emanations thus overlap and the entire area of the cancer is subjected to the treatment. In a cancer of the breast, for example, twenty-five needles can thus be plunged into the breast and others run horizontally through enlarged glands in the axilla. One of the illustrations shows four radium puncture needles thus implanted in a neoplasm in the tonsil, with safety threads attached to the needles. He warns that this radium puncture is so potent that it is harmless only by keeping the needles scrupulously from encroaching on sound tissue. The fifty cases he has thus treated in the last eight months are too recent for a final judgment as to the outcome; all were inoperable cases.

Radium Treatment of Cancer of the Esophagus.—Dufourmentel reports a few cases in which the patients have been relieved from pain, and swallowing has been improved, and there has been a gain in weight during the five months or more since radium treatment of the cancer of the esophagus is being systematically applied. Others have survived for from thirteen months to three years, and during this remission they were relieved of pains and dysphagia.

*Diabetes in Wartime. D. Gerhardt.—p. 141.
*Adaptation of the Parasite to Its Host. B. Galli-Valerio.—p. 143.
Getting Patients Up Early After Childbirth and Operations. Hâberlin.—p. 148.
*Tuberculosis and Abortive Treatment of Syphilis. Tièche.—p. 149.

Diabetes in Wartime.—Gerhardt observed eleven cases of diabetes in soldiers which began with high glycosuria and great loss of weight, but under dietetic measures it subsided to a final complete cure after return home. Emotional stress and nervous influences may have cooperated, but the diabetes was influenced by dieting as readily as any diabetes. In 11 cases of war diabetes in the Würzburg hospital, 2 died in coma within three months of the onset of symptoms; a third died in coma after a carbuncle although he had been in good condition notwithstanding high glycosuria for two years. The others improved under treatment and were discharged. Among the 16 civilian cases, 3 died in coma and 3 showed no

benefit from treatment, but all the others were materially improved. The dietetic restrictions of the war seemed to have rather a favorable influence on diabetes, and the lessons learned therefrom will benefit diabetics in future. Various explanations for this have been given, but Gerhardt ascribes it to the low calory content of the food, and especially the small proportion of albumin, and the large proportions of carbohydrate-containing vegetables. It is seen to be not necessary to exclude meat and cheese absolutely. The diabetics did even better on this diet than if they had conscientiously followed a strict antidiabetic diet without careful medical supervision. Too little carbohydrates may do harm as well as too much.

Adaptation of Parasites to the Host.—Galli-Valerio cites a number of observations in which it has been possible to trace the adaptation of a protozoan from the exterior to a casual host until it became an actual parasite; or, after being a parasite of one species, it adapted itself to another. The sequence is usually through the invertebrates to the vertebrates. His long review of the subject emphasizes anew the importance of comparative pathology and parasitology for human pathology and epidemiology. It shows how a new parasitic disease is liable to develop among us at any moment. Such was the case with the trench foot of the war. It shows further the danger for man from the widespread prevalence of flagellata among the invertebrates.

Tuberculosis and Abortive Treatment of Syphilis.—Tièche warns that abortive treatment of syphilis may be fraught with considerable danger when the patient is already tuberculous. The tuberculosis may be whipped up by the specific treatment of the syphilis, in some cases, while in others no effect is apparent. The combination of arsphenamin and mercury may upset the balance of antibody production. Special caution is necessary with an inherited taint. He advises extreme caution, bearing in mind that the syphilis is more amenable to treatment later than the tuberculosis, if the latter is roused to a progressive course, and also that the syphilis in itself does not have such an injurious influence on the tuberculosis as the means taken to abort it.

*Edema of the Larynx in the Pregnant. S. Pusateri.—p. 135.
Prophylaxis of Endemic Goiter. G. Cavina.—p. 137.

Special Corpuscles in Typhus.—Ficai reports finding in infected lice and in the brain of persons who had died at the height of typhus, numerous corpuscles of a diameter of 2 or 3 microns in the capillaries, but larger ones, round or oval, were found both in and outside of the large nerve cells of the cortex and of the nuclei of the base. Nothing resembling these corpuscles could be found in diseases other than typhus in his research.

Edema of the Larynx in the Pregnant.—Pusateri reports the case of a healthy woman of 30, with two healthy children, nearly at term with her third pregnancy. She had been exposed to scarlet fever, and suddenly developed acute edema of the larynx. Repeated attempts at intubation failed, while tracheotomy and means to hasten delivery were opposed by the family until the second day, by which time the fetus had died, and tracheotomy had to be done as a last resort. The woman died in coma in a few hours. The case teaches the necessity for prompt intervention with acute edema of the larynx in the pregnant; even intubation is liable to prove ineffectual. The danger to the fetus from the lack of oxygen, etc., justifies prompt artificial delivery. This not only saves the fetus but may have a favorable influence on the mother by the loss of blood and the rapid oxygenation of her blood. The pressure on the diaphragm from the pushing up of the viscera by the enlarged uterus hampers the functioning of the respiratory organs, and aggravates conditions from the acute edema.

*The Future of Medicine. A. Murri.—p. 1.

*Reproduction of the Malaria Parasite. T. Pontano.—p. 36.

The Future of Medicine.—Murri takes thirty-five pages to reply to Mackenzie's recent book with this title, which was reviewed in THE JOURNAL, Feb. 7, 1920, p. 415. He regards as extremely important Mackenzie's insistence that the future of medicine rests with the general practitioner; but he declares that Mackenzie goes too far in his effort to "simplify." To simplify too much is to retrogress. Murri also quotes from his own writings of thirty-three years ago describing what he called paralysis of the auricle, which has been recently rediscovered and entitled auricular fibrillation. Murri thinks that the practitioner will get a much better idea of the condition when it is called paralysis of the auricle than from the term fibrillation. He protests further against Mackenzie's assertion that there is always pain with incipient disease, citing a number of conditions, such as when albuminuria is casually discovered, in which there are absolutely no subjective symptoms.

Reproduction of Macrogametes of Plasmodium Vivax in the Blood Stream.—Pontano presents evidence of this occurrence in a case described, with a colored plate showing the gametes of *Plasmodium vivax* in different phases of reproduction, and says that even one positive observation outweighs a thousand negative findings. The attack of malaria was the first relapse after a latent interval of nearly five years.

Treatment of Latent Malaria. A. Jona.—p. 12.
*Protein Reaction and Fever. G. Galeotti.—p. 13.

Central Pneumonia.—Sofrè relates that he has sometimes had patients with high fever for several days, the face red, occasionally slight coughing, but none of the usual signs of pneumonia or of any other pulmonary disease could be detected. The course of the case, the increase in the cough, the progressively abundant expectoration, and the drop in the fever by crisis all testified to the correctness of the diagnosis of pneumonia and its central location. The extra resonance and the weakness of the vesicular murmur are restricted to one zone of the lung, usually corresponding to a single lobe, but there is nothing otherwise in the history to suggest emphysema.

Fever and Protein Intoxication.—Galeotti recalls that any heterogenous protein introduced parenterally in man or animals induces fever. On the other hand, in experiments on animals and in spontaneous fever in man, the fever every time could be traced to the presence in the organism of heterogenous or denatured or disintegrated, dead protein. Even exogenous poisons, he continues, never induce fever unless they modify the protein metabolism. Fevers can thus all be explained by this conception of protein intoxication. The heterogenous protein molecules can not be adsorbed, and they are thus unutilized, and they hamper the functioning of the cellular protoplasm. They may even exert a destructive action as they cling to the cells. This toxic action persists until by advanced hydrolysis the protein substances lose their colloid structure and become simple molecules (polypeptides and amino acids).

Functions of the Optic Thalamus. A. Jappelli.—p. 97.

Benzol in Leukemia.—Ravenna reports three cases of chronic myeloid leukemia in which benzol treatment was systematically applied. They show that extreme caution is necessary with it, and that the effect is purely symptomatic. The symptoms inevitably return, sooner or later, and in a graver form, against which we are disarmed. In the favorable cases, under benzol the drop in the number of leukocytes is proportionately greater, in the immature forms; more uric acid is eliminated and the leukopenia continues to progress after suspension of the drug. In one of his cases the leukocytes numbered 234,000 in the obese woman of 57. Under 80 drops of benzol daily, the number dropped to 8,800. After a few months of substitution of Fowler's solution for the benzol, the leukocytes ran up to 43,000 but were again brought down to 11,000 under benzol. Nine months later they again ran up but subsided again under two months of 80 drops of benzol daily. A year later the number was 11,000. After another year or two the leukocyte count was found to be 265,000, and the number then was not modified by benzol, but was brought down to 22,000 with two months of roentgen exposures, 3 H units at a sitting, and the general health improved. Necropsy in the two other cases failed to show any injury from the benzol, or special accumulation of leukocytes in any organ. One patient was a man of 35; roentgen treatment brought the leukocytes down from 400,000 to almost normal. After a few months the symptoms flared up again and vigorous benzol treatment induced only transient improvement, the man dying the fifteenth day of the acute exacerbation.

Signs of Hyperthyroidism in Early Diagnosis of Pulmonary Tuberculosis.—Gallotti describes six cases in which toxic action from the insidious tuberculosis induced a more or less complete hyperthyroid picture. The goiter was treated with electricity, and tonics were given. The results indicated that treatment of the thyroid in such cases is liable to have a favorable influence on the pulmonary tuberculosis. He has encountered so many cases of this combination that he now suspects pulmonary tuberculosis in every case of exophthalmic goiter until this can be excluded. His experience indicates further that enlargement of the thyroid seems to imprint a benign character on the tuberculosis.

Prophylaxis of Cerebral Hemorrhage.—Paoletti queries why hemorrhage in the elderly occurs only in the cerebral vessels and not in the vessels of the abdomen or limbs. It seems as if there must be some special condition in the brain which favors rupture of vessels. The condition peculiar to the brain is that the vessels are subjected to a constant pressure from the cerebral fluid, although the intensity of this pressure may fluctuate. It is possible, he suggests, that when this pressure is less than usual, the vessel walls stretch as they are released from the usual pressure, and, as they stretch, they rupture. This assumption of hemorrhage *ex vacuo* not only explains all the facts observed, but suggests that when symptoms indicate impending cerebral hemorrhage or minute extravasation has already occurred, intraspinal injection of a little artificial serum might restore the normal intracerebral pressure, and thus ward off future injury from this source. He thinks that at least it is worth a trial in institutions for the aged, in treatment and in prevention of apoplexy.

Electropuncture of the Spine in Tabes, etc.—Piccinino has found vigorous revulsion applied to the spine effectual in treatment of tabes, often curing the ataxia or other disturbances. He prefers for the purpose a needle connected with the negative pole. This induces an electrolytic action deep in the tissues, but strictly localized. The positive electrode is placed on the spine above or below, with continuous current from pile or battery, connected with street lighting current, with galvanometer and rheostat. In cases rebellious to courses of mercury, this electropuncture at the points most diseased seems to attract the drug to these points, and clinical improvement results. The negative pole branches and

this can be connected with two needles; one is inserted to a depth of 1, 2 or more cm. and a current of 10 or 15 milliamperes is turned on. The electrolysis causes bubbles of gas around the needle; when this occurs, the second needle is introduced and the first withdrawn. This avoids sudden shocks, and in this way from fifty to 100 punctures can be made at a single ten or fifteen minute sitting, under a local anesthetic and epinephrin. This method of intrapolar catalysis, he says, is applicable to any form of meningomyelitis, especially those with spastic phenomena.

Hyperplasia of Abdominal Lymph Glands.—Bourroul and do Amaral report the case of a boy of 9 who suddenly developed intense pains in the abdomen. An exploratory laparotomy the fifth day revealed merely enlargement of lymph glands, simple hyperplasia. The mesentery was studded with these enlarged glands, some as large as a pigeon's egg, compressing the bowel at different points. After the exploratory laparotomy, the pains gradually subsided and disappeared completely by the end of the second week. The boy had been given iodid, epinephrin, atropin and a single injection of arsphenamin. No attempt was made to remove any of the glands as sarcomatosis was assumed. Only microscopic examination of an excised scrap revealed the benign and curable nature of the lymphatism. The authors cite in connection with this case Symmers and Greenberg's study of lymphoid hyperplasia in the appendix, *THE JOURNAL*, Feb. 15, 1919, p. 468.

 *Endemic Goiter and Cretinism in Argentina. R. Kraus.—p. 309; Idem. R. Wernicke.—p. 325.

Encephalitis in Horses.—Kraus and his co-workers cultivated a diplococcus from the lesions of the brain in the contagious enzootic which for several years has been affecting horses in Argentina. The symptoms are explained by the infiltration of the cerebral vessels, and the presence of the diplococcus with which they were able to reproduce the disease in rabbits and in horses. Over twenty large photomicrographs accompany the article and seven illustrations of animals with the disease. It was first observed, they say, at Borna, near Leipzig, in 1894, and is usually called Borna disease.

Heterogenous Antibodies.—Sordelli and Pico found that when a hemolysin for sheep or goat corpuscles was added to a suspension in physiologic saline solution of an alcoholic extract of guinea-pig kidney tissue, in a few hours agglutination and precipitation occurred and the fluid became clear. They experimented with other lipoids and antigens, and explain the phenomenon as a reaction between an antibody and a heterogenous antigen. It does not occur in the absence of sodium chlorid.

Heterogenous Antigens.—Wernicke and Sordelli state that light is thrown on the nature of heterogenous antigens by their success in isolating a substance (containing nitrogen and phosphorus, with the property of fixation of heterogenous hemolysins), from an alcoholic extract of horse kidney tissue treated with acetone, ether and benzol.

Mixed Tumor in Rat.—Roffo gives eleven photomicrographs of a spontaneous carcinosarcoma found in an old white rat.

Vaccine Treatment of Whooping Cough.—The vaccine is made from sputum, and the impressions from this treatment were quite favorable, although Bacigalupo reports over 12 per cent. unmodified by it in his 495 cases.

Biologic Tests Show Kinship Between Species.—Fischer and Kantor found it impossible to induce anaphylaxis in various members of the cavy family. This negative response sustains their biologic kinship. They found further a similar analogous response to inoculation of transplantable guinea-pig lymphosarcomas, and also to the response to precipitin tests. The animals investigated were the guinea-pig and the cuis or *Cavia pallas*. The article is illustrated.

Endemic Goiter in Argentina.—Kraus states that no statistics have been compiled in regard to the prevalence, etc., of goiter and cretinism in Argentina, but that both are known to occur in the mountainous regions of the country while the Buenos Aires and Córdoba districts seem to be free from goiter. The insect host of Chagas' disease is prevalent, and it has been found at various points to be infected with the trypanosome, *T. cruzi*, which induces Chagas' parasitic thyroiditis. But Kraus does not know of any instance of Chagas' disease in Argentina, the endemic goiter and cretinism having apparently no connection with the trypanosome. The acute form of Chagas' disease as observed in Brazil is characterized by the thyroiditis and the presence of the trypanosome in the blood. The chronic forms may be confounded with endemic goiter and cretinism; the differential diagnosis is difficult in mountainous districts. It is possible that this South American trypanosomiasis is a superinfection of endemic goiter and cretinism. He urges research in this line to determine whether Chagas' disease is common in mountainous districts in Brazil where endemic goiter and cretinism abound, while it is absent from the plains—as in the Argentina flat country—notwithstanding the presence of

the infected insect host. Some of the illustrations show groups of cretins in the mountain districts and cretin dogs.

Endemic Goiter and Cretinism in Argentina.—Wernicke relates that the localities where goiter is endemic in Argentina have soil and waters that differ completely from those which Bircher incriminated in Switzerland as responsible for endemic goiter.

Leukocyte Count in Malaria. M. Stoss.—p. 1135.
Body Heat in Relation to Work. J. Fischer.—p. 1137.
Prevention of Infant Mortality. F. Lenz.—p. 1139.

Causes Producing Renal Calculi Following Injuries to the Spinal Column.—Holländer gives an elaborate and detailed explanation of the phenomenon to which Kurt Müller called attention in 1895, namely, that following certain injuries to the spinal cord, there is frequently a rapid and bilateral formation of calculi in the renal pelvis. He ascribes the condition to the paralysis of the renal pelvis and the ureter, resulting directly from the injury to the spinal column.

Early Diagnosis of Scarlet Fever.—Zuelzer endeavors to show that scarlet fever is recognizable in the incubation stage several days before the onset of the fever. He ventures in explanation of the maximal enlargement of spleen and liver at the onset of the fever in scarlatina, typhus and malaria the hypothesis that the causative agent attacks these organs first. He has found quinin treatment of scarlet fever efficacious in the early stages, and has effected cures by its use. As it is doubtless true that the disease is spread during the incubation stage, this constitutes an added reason for its early recognition. As a prophylactic measure he recommends that in every case of infectious sore throat large doses of quinin should be prescribed. If scarlet fever is not present, no harm is done; in fact, Fraenkel recommends quinin as the most rational treatment for angina. In Prussia the case mortality from scarlet fever before the war was 10 per cent. He states that percussion of the liver is facilitated by a deep inhalation, distending the abdomen.

*Potassium Permanganate Treatment of Smallpox. W. Bender.—p. 1160.
Value of Liquor Carbonis Detergens. Herxheimer and Altmann.—p. 1162.

Pathogenesis of Blackwater Fever.—Zlocisti expresses doubt whether on the basis of the known material a uniform genesis for all cases of blackwater fever can be established. He endeavors to show that the theory that blackwater fever is due to the harmful effects of quinin administration is untenable, by citing a special case in which grave hemoglobinuria developed when no quinin was being taken and it subsided under large doses of quinin.

Hemolytic Phenomenon of Urine in Chronic Nephritis.—Neufeld calls attention to a peculiar phenomenon occurring in a case of severe nephritis as revealed in the serologic examination of the urine of a series of syphilitics. The volume of albumin in the urine of the patient in question was 0.7 per cent. The Wassermann reaction in the blood was strongly positive; in the urine, absolutely negative. This negative urine reaction as opposed to the strongly positive blood finding contradicts, he thinks, the usual serologic findings in other body fluids containing albumin. Investigation revealed the fact that the urine contained a very active hemotoxic substance, laking sheep blood and beef blood but not human, guinea-pig or rabbit blood. He found further that this hemotoxic substance seems to have nothing to do with syphilis but is often found with severe nephritis, especially in cases with manifestations of uremia. The hemolytic substance is not destroyed by boiling. It seems to occur proportionately to the albumin content of the urine.

Potassium Permanganate in Treatment of Smallpox.—Bender condemns red light therapy and endorses the potas-

sium permanganate treatment of smallpox as effective in dealing with the dermatologic aspects of the disease. The convalescent stage is much shortened on account of the accelerated desquamation process, especially if the peeling of the palms of the hands and the soles of the feet is aided by mechanical removal. The isolation period is reduced, which lessens the number of melancholy states and hysterical attacks. Dreyer has the face, arms and hands painted with a saturated aqueous solution of potassium permanganate three or four times a day for the first two days and then the entire body once a day. This stains the skin brown and thus realizes a kind of colored light therapy, he says, besides its other advantages. Bender found it impossible to apply the solution so often or in such concentration, as it caused smarting, but by diluting it and applying it to part of the body at a time, he obtained excellent results in his eight cases.

*Pityriasis Rosea and Trichophytosis. Fried.—p. 1423.

Variable Virulence of Tubercle Bacillus Infections.—Hauser reports as the result of animal experimentation that the virulence of the human type of tubercle bacillus found in various cases of tuberculosis in man varies between very wide limits. Strains of weak virulence after repeated introduction in the eye of a rabbit regain the average virulence for a rabbit's eye. In acute military tuberculosis the virulence of the tubercle bacillus may be unusually low.

Diagnostic Significance of Sarcinae in the Stomach.—Gerhardt states that it has been his experience that sarcinae in the stomach may always be taken as an indication of stasis, usually from organic pyloric stenosis, accompanied by considerable gastrectasia. In some cases the stasis was only temporary, caused partly by slight organic changes combined with reflex spastic closing of the pylorus, and partly the result of motor insufficiency due to acute gastritis. The amount of free hydrochloric acid present seemed to have no bearing on the colony of sarcinae.

Pulmonary Syphilis.—The fact that pulmonary syphilis is often overlooked clinically, and that it is so commonly mistaken for pulmonary tuberculosis has led Schröder to endea-

vor to clarify in some measure its clinical picture. The most important means of establishing a differential diagnosis is the roentgen ray. An exact anamnesis is important. Syphilitic changes in the upper respiratory passages and elsewhere should be looked for. The localization, or atypical seat, of the lung process is significant. Absence of tubercle bacilli should be weighed. A more protracted course than in tuberculosis should be noted.

Neuroses of the Diaphragm.—Jamin recalls that the diaphragm, owing to its position between voluntary and involuntary muscles and forming a partition between the abdomen and the thorax with its own sensory innervation, is not infrequently the seat of psychogenic sensory and motor disturbances, in which the thoracic and abdominal muscles are involved in various ways. The resulting neuroses may easily lead to diagnostic errors as to conditions in thoracic and abdominal organs, the functioning of which may in fact be thereby impaired. Early diagnosis and psychotherapeutic treatment of these neuroses are therefore essential. Systematic breathing exercises will exert a prophylactic influence, and, while valuable for all, they are especially indicated for young persons who are weakly and nervous.

Intermittent Therapy: Value of Intervals Without Treatment.—Königer thinks that too little attention has been paid in the past to the value of rest periods, or intervals without treatment, which his investigations and observations would lead him to regard as an integral part of therapy. The periods of suspension should be as carefully investigated as the choice of a remedy, its dosage and manner of administration.

Inunction Tuberculin Treatment of Surgical Tuberculosis.—Heubach states that he has been using the Petruschky method since April, 1918, in both hospital and private practice, having given this treatment in eighty cases of tuberculosis of the lymph glands, forty-five cases of tuberculosis of the bones and joints, and in five other isolated cases. More than 50 per cent. of the cases were grave, and only 5 per cent. were mild. In every case he was impressed with the favorable effect on the course of the disease. The usually intractable fistulas in tuberculosis of glands and joints, and the abscesses in vertebral tuberculosis healed after the second or third tuberculin inunction. In a few cases a second series of treatments following a four to eight week interval became necessary, but he seldom failed to secure the desired results. Many of the severe cases he would formerly have regarded as hopeless. Sufficient time has not elapsed to speak of the percentage of permanent cures. He considers the beneficial effect of the treatment to be indirect, in that it strengthens the natural resistance of the organism.

Infants Born During War Period.—Jahreiss considers the question as to how the development of the fetus is affected by the changed nutrition of the mother. The results of his investigations on children born in the Augsburg Maternity during 1918 and the first seven months of 1919 are to the effect that the children born during this period were perfectly normal in weight, length and size of head.

Acute Participation of the Ovary in Epidemic Parotitis.—Ruge reports an acute condition of the ovary which arose in the course of mumps. There were symptoms of internal hemorrhage which precluded a diagnosis of acute oophoritis and favored ovarian hematoma; or possibly a combination of the two. Five weeks after it was first discovered the ovary had returned to normal size.

Treatment of Pityriasis Rosea and Trichophytosis.—Fried recommends mercurial ointment for the treatment of pityriasis rosea and trichophytosis, as it effects a speedy cure and is cheaper and simpler than the roentgen ray.

Quinin in Childbirth. L. Knapp.—p. 1185.

Traumatic Purpura. R. Gruss.—p. 1185.

*By-Effects with Smallpox Vaccination. K. Wagner.—p. 1186.

War in Relation to Hereditary Syphilis.—Hochsinger, basing his opinion on investigations applied to 123,284 births in Vienna, reaches the conclusion that syphilis among the newborn and infants decreased during the war period.

Unusual Effects of Epinephrin in the Elderly.—Arnstein and Schlesinger record that sometimes, following subcutaneous administration of epinephrin in elderly patients, the blood pressure drops, either with or without a preceding brief rise. In many cases this is associated with cardiac weakness, in which case tachycardia commonly results. Or the response may be bradycardia for several hours, often without accompanying decrease of blood pressure.

Lung Enlargement in Syphilis.—Edelmann reports on the basis of extensive investigations that tertiary syphilis may lead to lung changes in the nature of lung enlargement and emphysema. This finding, he thinks, serves to throw light on a certain proportion of the cases of so-called idiopathic emphysema occurring in middle life.

Observations on Smallpox Vaccination.—Wagner reports some peculiar phenomena following vaccination for smallpox in a woman of 36, who, with the exception of hay-fever, from which she had suffered since she was 14 years old, was perfectly healthy. She had been vaccinated two years previously without success. Following revaccination in July, 1919, with the appearance of the pustule, doughy swelling of the skin developed over the whole surface of the body. The patient was unusually pale and listless. Temperature ranged between 37.5 and 38.8. Marked dyspnea was present and the pulse was slow and tense. Respiration was asthmatic. The tonsils were somewhat enlarged and covered with grayish-white spots. The liver was enlarged. Specific gravity of urine was from 1.009 to 1.018. The albumin content was 0.05 per cent. and remained at this level for several days. There were no casts and no red blood cells, but renal epithelial cells were present in considerable numbers. The affected arm was red and swollen. These inflammatory phenomena disappeared in a few days without treatment. Wagner raises the question whether the hay-fever could have been in any way connected with the phenomena. Sore throat was observed in five other cases of the series of thirty and accompanied by a still higher fever (up to 40.2 C.). The sore throat yielded readily to local treatment. Sore throat was not epidemic at the time, nor were the weather conditions such as to favor its development. During this same period of vaccination, cases of severe illness and even fatalities following vaccination were reported from other sources.

- *The Tuberculous Psychoneurosis. G. Ichok.—p. 334.
- Repose versus Occupation in Treatment of Pulmonary Tuberculosis. H. Hayek.—p. 350; Idem. H. Maendl.—p. 352.

Treatment of Pulmonary Tuberculosis.—Köhler declares that sanatorium measures are often applied too arbitrarily. The patients may actually suffer from cold, when reclining or sleeping out of doors. "The exposure of the décolleté gowns of the present day may be extremely harmful for anemic and tuberculous girls and women. . . . Toughening procedures have their day before 35 for the healthy, but after this the aim should be to spare the organism, and chief among the measures for this purpose is a proper supply of warmth. This is particularly necessary for persons with poor blood, the tuberculous, the nervous, the rheumatic, and those with disease of the kidneys or sexual organs."

The Tuberculous Psychoneurosis.—Ichok insists that the tuberculous psychoneurosis is a characteristic syndrome which requires individual treatment and is of general social importance. Pronounced psychoses are rare in the tuber-

culous, but this psychoneurosis is extremely common. Toxic action from the tuberculosis toxins cannot be alone responsible, as the psychoneurosis does not necessarily become more severe as the intoxication progresses, while, on the other hand, the psychoneurosis may develop complete even with the mildest forms of the disease. Ichok ascribes it mainly to a subconscious sense of organic inferiority (*organminderwertigkeit*). The source of the psychoneurosis should be sought, possibly by psychanalysis, to enable the patient to divert his mental processes into useful channels.

Closing an Artificial Anus. J. Kinscherf.—p. 151.

Anastomosis for Volvulus of the Sigmoid Flexure.—Pochhammer sutures together, side to side, the lowest parts of the loop that he has just untwisted. The anastomosis opening must be 6 or 8 cm. long, to allow free passage of the contents. The loop above is thus functionally excluded, and it finally nearly shrivels away. He has thus treated four patients with volvulus of the sigmoid flexure in the last two years. Other technics expose to danger of recurrence, while with this method recurrence is impossible.

*Operation for Undescended Testicle. P. Frangenheim.—p. 173.
Orchidopexy plus Funiculopexy for Testicle Retained in Inguinal Canal. E. Glass.—p. 174.

Habitual Dislocation of Patella.—Marwedel says that he knows of fifty different methods for correction, but that the technic he describes here is superior to all others. He slits the capsule and laps the lips in a special way as he shows in his illustrations.

Cure of Postoperative Tetany.—Haas was able to cure the tetany and bring it on again at will in a severe case by administering beef parathyroid tablets. In a short time the patient's own parathyroids had recuperated; they had only been damaged, not removed, at the goiter operation. Haas adds that in resecting the thyroid in a woman seven months pregnant, he found the parathyroids three or four times their normal size, and regards this as a hint to give parathyroid treatment to pregnant women showing signs of parathyroid insufficiency, and to keep it up until far into lactation. Or grafting of parathyroids might be considered. There is no theoretical ground for giving thyroid treatment alone in tetany; the thyroid may actually annul any action from the parathyroids.

Simplified Operation for Undescended Testicle.—When Frangenheim finds it difficult to bring the testicle down to its proper place, he lengthens the spermatic cord by shifting its position to back of the epigastric vessels, thus shortening its course without injury to the elements of the cord. The testicle is easily drawn through behind the inferior epigastric artery and vein, as he explains with an illustration. The procedure is much facilitated by raising the pelvis quite high. He has applied it successfully in ten cases.

*Operative Treatment of Incontinence of Urine. A. H. M. J. van Rooy (Haarlem).—p. 192.
*Endemic Diphtheria in Maternities. E. Hollatz.—p. 195.

Operation for Incontinence of Urine.—Van Rooy applied the Goebell-Stoeckel technic in a case of incontinence of urine that had resisted all treatment for sixteen years. It had followed forcible removal of a calculus from the bladder. A flap of muscle was brought down to each side of the neck of the bladder, working through a transverse incision above the symphysis. Then, through an incision in the vagina, the ends of the muscle flaps were sutured together around the

neck of the bladder to make a new sphincter, as it were. Eight months have passed since the operation, and there has not been a trace of incontinence since. The patient, an unmarried woman of 36, urinates only every three and a half or four hours. The muscle loop draws the neck of the bladder upward, and this partially kinks it. The pyramidalis was the muscle used to reenforce the sphincter.

Endemic Diphtheria Among the Newly Born.—Hollatz states that since 1910 thirteen reports have been published of epidemics of diphtheria among the newly born. In nearly all the cases the nose was the seat of the process.

Isolated Compression of Abdominal Aorta. J. Suerken.—p. 223.
Amniogenous Deformities. C. v. Goetzen.—p. 225.

Hydraulic Turgidization of the Placenta.—Schwarz extols Gabaston's method of injecting a fluid into the placenta as a simple and harmless means to arrest hemorrhage and aid in the spontaneous separation of the placenta. He has applied it in sixteen cases. As the placenta swells from the injected fluid, the effect in detaching it from the uterus wall is the same as when the uterus wall contracts under the placenta, while the distention of the placenta stimulates the uterus to contract, and its heavier weight exerts greater traction. A still further advantage is that the turgidized placenta offers a better hold for the hand in case continuance of the hemorrhage demands Credé expression. The saline is injected through the umbilical cord vein until some resistance is felt; usually 300 or 400 c.c. are enough. It never seemed to do any harm in his cases. (Gabaston's original communication on this hydraulic method of aiding in detaching the placenta was summarized in THE JOURNAL May 2, 1914, p. 1443.)

- *Immunity of Common Fowls to Plague. P. C. Flu.—p. 116.

Immunity of Fowls to Plague.—Flu inoculated ten hens or cocks with a fraction of or one or two loops or a whole slant culture of plague bacilli of a strain which killed guinea-pigs in a 1:10,000 loop dose injected subcutaneously. The fowls were inoculated by the vein, subcutaneously or intramuscularly, but none showed signs of sickness, phagocytosis always insuring the prompt disappearance of the plague bacilli. They retained their virulence to the last, up to four days, but all seemed to act merely as foreign bodies, and were incorporated by the phagocytes. Domestic fowls, he states, have a temperature of 42 C., and he regards this as significant, as he, Kolle and Strong have noted that the plague bacilli rapidly decrease in virulence when cultivated at a temperature as high as 40 to 42 C.

Wassenaar's Visual Phenomenon. S. J. R. de Monchy.—p. 129.
*Treatment of Lupus. P. J. Mink.—p. 130.

The Campaign Against Venereal Disease.—Van Leeuwen reiterates that the efforts to deprive venereal diseases of their endemic character require the personal cooperation of medical men. It would result in incalculable advantage if all would keep a record of every case, especially of syphilis, and record the effect of the disease on the patient and on his family as the years pass. He appeals to physicians in general to aid in this and in other ways the organized efforts to repress the spread of these diseases.

The Shape of the Normal Stomach.—Van Lier compares the conflicting statements of various authors as to the shape of the normal stomach, saying that the shadow cast when the stomach is weighed down with a suspension of bismuth cannot be accepted as the normal finding. Even the necropsy findings do not represent the physiologic stomach; the rigor mortis, the gases that may form in half an hour after death,

and other factors distort the shape of the stomach. He gives roentgenograms of the dog stomach, after a fine rubber tube filled with a contrast suspension had been sutured to the outside of the stomach from the esophagus to the pylorus. The shadow of the fasting stomach shows the rubber tube crumpled up in a bunch, the fasting stomach having evidently contracted into small compass. With the heavy contrast meal, the stomach assumes a sac shape, with a tube shape at the pylorus end.

Prophylaxis of Whooping Cough.—Enklaar suggests that contagion of whooping cough and possibly of measles might be prevented by arranging the classes according as the children have had the disease or not. If a case develops in a school room, those who have had the disease can continue at school, but the susceptible should be kept at home until the danger of contagion is past.

Acid Treatment of Lupus.—Mink applied trichloroacetic acid in a case of lupus refractory to light treatment, and was surprised at the prompt benefit.

*Prophylaxis of Venereal Disease. H. T. M. van Leeuwen.—p. 201.

*Functional Dyspepsia. C. G. Vervloet.—p. 207.

*Epidemiology of Cholera. C. S. Stokvis.—p. 216.

Contract Practice in Rural Districts. H. C. van den Bijlaardt.—p. 223.

Prophylaxis of Venereal Disease.—Van Leeuwen enumerates the reasons why he rejects as bound to prove ineffectual any official recommendations for individual prophylaxis among civilians. His five years' experience as secretary of the Netherlands Society for Combating Venereal Disease has convinced him that the best plan is for the authorities merely to enjoin abstention from extramarital intercourse in prevention of venereal disease, but to provide ample facilities for medical care at suitable hours and places for the infected, leaving it to the physician in charge to decide whether in a given case it is necessary or useful to apply local preventive measures. Van Leeuwen makes a point of always carefully instructing in the first signs and symptoms of venereal disease, and in the danger of infecting others during these six or eight weeks.

Functional Dyspepsia.—Vervloet remarks that the diarrheas from insufficiency of the digestive glands form the largest contingent of the cases of functional intestinal derangement. The glandular secretions may be deficient in quantity or quality. He found gastric achylia or hypochylia in 25 of 84 cases of fermentation diarrhea, and in 6 cases the pancreas also was functionally insufficient. Undigested starch and much cellulose in the stools should suggest investigation of the chemistry of the stomach, and in 30 per cent. some secretory anomaly then becomes evident, as a rule. Treatment to substitute the lacking gastric juice soon improves the diarrhea. Diarrhea from putrefaction processes or defective digestion of fats is seldom found with achylia, and the products are less irritating than the acids generated in the fermentation processes. He never saw a case in which the intestinal disturbances had preceded the hypochylia, but was able to trace the reverse sequence very plainly in two cases; the defective functioning of the secretory system of stomach and pancreas had preceded the colitis, with a catarrhal intestinal condition bridging the intermediate period. In 32 cases of diarrhea with gastric achylia or hypochylia there were only 8 in which there was distinct putrefaction; in the other 24 there was abnormal fermentation. The abnormal fermentation of carbohydrates and cellulose forms the link between the gastric achylia and the colitis. Perhaps investigation of other digestive ferments may throw further light on functional dyspepsia. In treatment, bed rest will often be found a valuable adjuvant. The findings in the stools should guide the diet.

Epidemiology of Cholera.—Stokvis insists that nowadays we pay too exclusive attention to bacteria, and overlook other circumstances that may have a causal or accessory significance. We should study epidemics by a "mass epidemiology" instead of by individual cases. Of course when the epidemic has once got a firm foothold, it is spread by contact, but this is inadequate to explain the earlier phases.

*Masks in Prevention of Contagious Disease. A. Josefson.—p. 113.

Masks in Prophylaxis of Contagious Disease.—Josefson had masks used by the nurses in his service almost from the beginning of the influenza epidemic, and states that none of the nurses in the influenza wards contracted the disease, as all scrupulously wore the masks. In the adjoining surgical ward, where masks were not worn, some of the nurses were down with the disease all the time. The wearing of masks with whooping cough, diphtheria, scarlet fever, mumps, etc., he observes, might arrest the spread of the infection. In conclusion, he warns that pregnant women should be protected with special care against influenza.

*Roentgen Ray Diagnosis of Gout. Hans Jansen.—p. 217.

*Huge Cavities in Lungs. F. Tobiesen.—p. 221.

Lethargic Encephalitis. H. Jacobsen.—p. 227.

*Perirectal Carcinoma. L. Melchior.—p. 231.

Roentgen Ray Diagnosis of Gout.—Jansen's roentgenogram of the hand of a man of 47 showed callus-like masses of bone and destructive processes—the picture not fitting into the frame of any known disease except gout, and it was on an unprecedented scale for gout.

Large Cavities in Lungs.—Tobiesen reviews the necropsy findings in five of six cases of a large cavity in one lung, and compares them with six cases on record, all on the left side. In the majority, the huge cavity had been mistaken for pneumothorax. In one of his five cases the cavity was on the right side. In all, the entire lung or nearly the whole lung formed a cavity traversed by trabeculae which corresponded to the vessels.

Perirectal Carcinoma.—Melchior recalls that cancerous stenosis of the intestines practically always has been explained by a cancerous growth in the bowel mucosa or secondary fibrous bands. The conditions were different in three cadavers recently examined; the rectal mucosa was intact, and the stenosis was the result of a metastatic carcinomatous infiltration of the connective tissue around the rectum and encroaching on it. In one of the cases the conditions had compelled a laparotomy, and the patient, a previously healthy man of 55, died. The primary cancer was a very small neoplasm in the esophagus which had not caused any clinical symptoms at the time of death. The "periproctal cancer" and tendency to stenosis was a necropsy surprise in the second case—a woman of 33 with multiple metastases of a mammary cancer—and also in the third, a man of 68 with gastric cancer.

*Intestinal Contents of Mummies. J. W. S. Johnson.—p. 326.

Immunity After Influenza.—Hall states that at the Bispebjerg hospital among the 500 patients with influenza in four weeks early in 1920, 8.2 per cent. had had the disease during the 1918-1919 epidemic.

The Intestines of Mummies.—Johnson relates that the mummies found in the excavations at Nagaed-der in Upper Egypt had not been embalmed. The intestines contained relics of grains and epithelial cells of a common plant, the trichodesma, which is a household remedy to this day in certain countries for intestinal irritations and catarrhal conditions of the air passages. He believes that the plant had been taken as a medicine because it was not found regularly among the eighty mummies, only in a few, and in three it was accompanied with mouse bones which are known to have been used medicinally by the ancients. The alkali of the bone powder was accompanied with scraps of cyperus and trichodesma. These mummies date from before the embalming period, more than 5,000 years B. C.

THE OBLIGATIONS OF MEDICINE IN RELATION TO GENERAL EDUCATION

PRESIDENTIAL ADDRESS *

W. C. BRAISTED, M.D.

Surgeon-General, U. S. Navy

WASHINGTON, D. C.

In the old Navy a midshipman was defined as a person with no rights and few privileges. Many societies and associations have a feeling akin to this about their president and regard him as a sort of lay figure on which to drape honors but from whom no serious participation in affairs is expected. It is no empty honor and no small privilege to be permitted to address the American Medical Association. I hope no one will think that I am exceeding my rights or straining my privileges in taking for discussion a subject which has been largely entrusted, during the Association's long campaign for the education of the public and the improvement of our medical schools, to members having special knowledge and special ability. It is my good fortune to be granted the floor here this evening, and I firmly believe that, while leadership belongs to the few who enjoy peculiar qualifications, intelligent cooperation is the obligation of all; that if the measures concerted in committees are to succeed they must have behind them the force of general approval and of lively interest in proportion to their importance. I therefore conceive that it is my part to foster by every means in my power a general participation in the educational program which has characterized this Association since its inception.

It is glorious to think that the practical, material benefit which we anticipate from this meeting is only secondarily for ourselves. We want to be more capable in the service we render to our patients rather than to increase either fame or fortune. This is very well as far as it goes, but it is not enough. We must realize afresh at each annual convocation that before being members of the Association we are physicians, before physicians citizens, before citizens men. So far as we neglect the functions of the citizen or forget the obligations created by man's social environment and repudiate every duty not directly connected with private practice, we are recreant to a high trust.

In the recent war the medical men of America laid aside their practices at no small sacrifice and with no small risk to their future prospects to play the patriot; and so did lawyers, business men, teachers in colleges,

scientific investigators, and so on. It was a noble stand to take, but the glory of this spontaneous uncalculating action will be considerably dimmed if, now that the threat of invasion, the foreign menace to our institutions has passed, we relapse into that narrow life pursued by so many who tacitly maintain that because they sustain important private relations to the sick they are absolved from participation in the struggle for the betterment of town, city, county, state and country, and of the world itself.

In this matter of responsibility outside of mere professional life we all need education, and what more fitting opportunity than this to solicit from you all a holier dedication to your patients' interests by thinking of what they need to be told, how they should be guided and how helped when they are not actually suffering from bodily ailments? When we do this we are at the threshold of social and preventive medicine—a medicine of education as well as of prescribing and operating.

EDUCATION OF THE PUBLIC IN HEALTH MATTERS

The education of the general public in matters relating to health has not been entirely overlooked in the United States. A good deal has been done, especially in the last few years, but the sum total is small indeed when considered, on the one hand, in relation to the importance of the subject, and, on the other, to our great territory, huge population, vast resources, multiplied and highly productive forms of energy and our general advance along all lines. Certainly in many details of health regulation and health promotion we are behind the older nations of Europe, relatively if not absolutely. True, we have an infinity of things to enrich and brighten life which they lack, but these have resulted from a desire for comfort and the reduction of manual labor, and have not grown out of the pursuit of health, which, as a matter of fact, is not always enhanced but may be seriously jeopardized by ease and luxury.

After the dissipation of life incident to all great wars, men invariably turn to the importance of saving life and prolonging it, and health-giving measures excite at least a temporary interest. We shall therefore miss a great opportunity if we do not at this time use every endeavor to press home the great self-evident truths about health and long life as they affect national prosperity and race permanence.

Is there any one who doubts for a moment that the physical integrity of its citizens and their ability to deploy all the energy which unvitiated, untainted nature can generate are of the first importance for the onward and upward progress of this republic? Is the health of the nation a national concern? If so, then the nation as such should go into the matter with the same busi-

* President's address before the American Medical Association at the Seventy-First Annual Session, New Orleans, April, 1920.

ness acumen, on the same scale and with the same continuity of effort manifested in any other vital public concern. There is certainly no occasion to advance arguments on this score. No educated and thoughtful man can deny that physical stamina plays an enormous part in the prowess and permanence of peoples. We see families, tribes and races spring up from a mysterious, nebulous origin that baffles alike the research of the philologist and ethnologist, reach a climax of development and power, and then decline. These fluctuations of fortune are genetically connected with physical conditions such as geographic location and its corollaries climate, food supply, parasitic infections, local foci of disease and perhaps the necessity for more or less consanguineous marriages. As a result of local conditions unfavorable to the propagation and perpetuation of a race, religious and social usages are evolved which form a sort of counterpart to those protective physical processes seen everywhere in nature.

One of the most remarkable and anomalous incidents of history is the way the Hebrews have preserved their race entity and characteristics though deprived for two thousand years of a local habitation and though prior to their final dispersion they had been for centuries the objects of foreign domination—enslaved, driven out, carried into captivity. While today the Jews may enjoy the benefits of other civilizations than their own, it is generally recognized that in the earlier periods of their history their cohesion and their national achievements were largely the result of a unique and remarkably extensive hygienic and sanitary system far beyond anything employed by any other race. Their peculiar observances were not due to the influence of physicians, to whom there is scant and none too favorable reference in the Old Testament, but embodied the wisdom of Egypt and Mesopotamia and had behind them the force of civic and religious obligation and were administered by the priestly caste. Carl Sudhoff of Leipzig, the modern authority on medical history, has characterized the Hebrew Sabbath day of rest and the direct prophylaxis of disease as the two greatest hygienic thoughts of mankind.

THE STATE'S NEED OF STURDY MEN

Can we pretend for a moment that the stability of Rome through twelve centuries of existence under kingly, republican and imperial rule, vexed by enemies within and without, was not dependent in a large degree on the extensive municipal provisions for health, which included an ample and excellent water supply, adequate drainage, extramural sepulture, and on the universal respect for physical prowess and physical hardihood inculcated by kings and consuls and not by the physicians, who to their lasting shame cared little for these things? We know how much the national life of Sparta owed to its rigid discipline and the paramount emphasis laid on bodily vigor, and how Athens all through its glorious period of intellectual development continued to cultivate physical perfection, not only because the artistic sense of the Greeks was gratified by beauty of form and symmetry of proportion but also because the old Homeric and pre-Homeric belief still survived that the deformed or depraved physique was to some extent an index of mental abnormality and moral blemish. In all this we are not up to the level of the Greeks of 500 years before Christ; for while science has gone far toward

demonstrating the extent to which conduct and happiness depend on conformation and structure, we do practically nothing about it.

To my mind the most paradoxical feature of our modern civilization is the indifference of a comparatively educated and well informed world to the human body, which is the most marvelous of nature's products and has been styled by Sir James Paget "the most complex mass of matter in the known world."

We are astonished when we reflect that man inhabited the earth and examined himself and his surroundings for thousands of years without discovering what seems to us so evident a thing as the circulation of the blood. But is it not extremely likely that future ages will comment with astonishment and scorn on our stupidity in not carrying on as a nation a systematic effort to improve physical development and to further physical conservation; in allowing our children to grow up in utter ignorance of their bodies and, if ignorant, necessarily neglectful of them?

I submit that the nation's health is a national concern; that it underlies all industrial and business effort; that it is the fundamental element in successful competition with rival nations, whether under the slow and prolonged strain of commercial contests or the sudden and imperious demands of armed conflict; that if we look ahead, as true love of country compels us to do, and estimate the trend of future events, we must acknowledge that physical vigor will, in a large measure, decide our complete development and permanent possession of the land which our forefathers won for us not only on the fields of battle but in strenuous struggles against the elements; in the mighty labor of felling forests, tilling the soil and developing the resources hidden in the heart of the earth.

I am very far from undervaluing the work of the many agencies already engaged in indoctrinating the people in the fundamentals of health; but it is undeniable that so far their efforts have been inadequate to the magnitude of the task as I conceive it. The campaign must be one of concerted measures, nationwide in extent and unflinchingly prosecuted.

TEACHING OF HYGIENE IN PRIMARY SCHOOLS

I think that up to the present we have been guilty of a cardinal error in seeking wholly to proselyte the adult. Our preaching has been to people enslaved by the chains of lifelong habits. We have advised men with damaged hearts and kidneys and blood vessels to eat and drink and smoke less; to take moderate exercise; to learn to relax and play; to avoid undue excitement so that they might spin out the thread of life by a few years. We have appealed to high school, college and university students to abjure tobacco and alcohol; have held up personal purity as something of supreme importance, given instruction about venereal diseases, instituted courses in personal hygiene that perhaps conveyed to them for the first time in their lives some rudimentary knowledge of their own bodies. In all this we have overlooked two things. The man of middle life cannot make his depraved body over and replace worn out organs. If he stops work he dies for lack of occupation. If he gives up some habit that has become an integral part of his being, he may suffer devitalizing mental and bodily reactions not unlike those of the opium eater deprived of his drug. The best he can do, and what he is most likely to do under the influence of this health propaganda, is to plan to

bring up his children on the lines suggested. This would seem at first blush to be a very definite and valuable result; but whoever has attempted in his own family to reform modes of living, whether in the matter of food, dress, ornaments, study or pastime, knows how difficult, how nearly impossible it is to accomplish any radical change which differentiates wife and children from the bulk of their associates and makes them the objects of comment. Young people are more gregarious than adults, and far more bound by the ethics and standards and practice of their kind.

In the second place we forget the pitiless logic of youth. The lad or maiden who has for five, ten or fifteen years been goaded to study grammar, mathematics, languages; on whom there has been exerted insistent pressure to acquire mental attainments, cannot easily be persuaded later on that a subject kept in the background or displaced in favor of something else is the one of paramount importance. We cannot expect the young to believe that hygiene, physiology and health are matters of prime importance; that their parents and teachers really esteem them such, when everything else has come ahead of these subjects. The children are right, because we do put first what we esteem to be first. They infallibly consider that health teachers are mere faddists and reformers, and that it is more vital to the gratification of their ambitions and their success in life to know the length of the Amazon and to be able to give the order in which different politicians have occupied the White House than to understand the oxygenation of the blood or the nature of a reflex movement.

I propose that we abandon at once all half measures, get away from routine, conventional methods and embark on something new, radical, revolutionary, but something at the same time perfectly feasible, if undertaken on a scale fully commensurate with the colossal results desired. We recognize that the nation must be composed of individuals having a maximum of physical strength and we believe that these individuals must be carefully educated; that is to say, mentally and morally developed, if we are to be something more than the world's bully, and if America has a destiny and a mission related to the world's ultimate amelioration. But just as our race as a whole must have physical integrity for survival in the struggle with its rivals, so the individual must have health and strength as a groundwork for all mental development.

SOUND HEALTH THE FIRST REQUISITE OF A LIBERAL EDUCATION

Let us throw out as irrelevant and misleading the occasional benefits conferred on humanity by the prodigious accomplishments of some individual whose genius bordered on insanity; let us forget that here and there an invalid, a neurasthenic, a neurotic has enriched the intellectual life of the world or done some epoch-making thing. Such facts do not invalidate the general proposition that sound health is the first prerequisite of a liberal and rounded education, and let us as a nation proceed henceforth not simply to give intellectual adherence to that proposition but to act on it. In other words, let us begin the child's education by teaching him health before everything else; first in point of time, first in importance.

Our primary schools have received not a little attention lately. They are better built and have better lighting and ventilation than in the past. We examine

the pupils for enlarged tonsils, bad teeth and granulated lids. We are instituting various commendable reforms, which should be continued and expanded, but they all belong to what might be called an extrinsic method of procedure. We must have something intrinsic. We must get possession of the child himself, affect his inner consciousness, modify his personality and give his life a definite bent, so that he will progressively and increasingly contribute by his own efforts to secure and preserve the health indispensable for the fullest use of the opportunities of high school, college and university. One of the most valid arguments against the higher education of women is the well recognized fact that the intense mental application of the really serious student is often accompanied by suppression or irregularity in certain important bodily functions. Therefore, an accumulated reserve fund of health, and habits of health, are as essential to her success at college as the girl's ability to pass the entrance examinations. It is too late to acquire health habits when the need for them begins to be felt, nor can we impart a proper sense of the importance of our health message to the high school girl if we wait until she is 16 to deliver it.

The primary school is universally recognized as the place to acquire certain things indispensable to future mental development and ultimate success. There is world unanimity about these essentials, but how common it is to have to take children out of school for reasons of health before they have got well into the three r's—reading, writing and arithmetic. What I propose is to go back of the three r's and begin all education by instilling into the child before he can read or write some knowledge of the human machine and the laws that regulate its upkeep; to elaborate and intensify this teaching step by step with other instruction, showing by practical illustration how to obtain the maximum yield from this machine.

Childhood is the habit-forming and the impressionable age. Churches wisely recognize this, and by means of the catechism, the Sunday school, and numerous other direct and indirect influences, seek to fashion the plastic mind and heart of the young into harmony with their worthy purposes.

In our plans to develop citizens with a proper sense of their public duties and privileges we take advantage of many of the instincts of childhood. We exhibit the flag, we have the children sing patriotic songs; later we give them outlines of community interests and civic economics. Occasions of national importance, military parades, the presence in the locality of some great public character are seized on to arouse and develop the patriotic spirit. But so far we have not gone to the root of the matter or seriously attempted to make health and the health cult the foundation of the child's education, which I conceive to be the only way by which later we may have lawmakers and law-abiding people who will put healthy living ahead of every other kind of living. The beginning should be made in the kindergarten, where already something is accomplished toward teaching appreciation of form and color; but the wonderful opportunities of this golden period are otherwise almost wholly thrown away. In kindergartens and primary schools singing might with propriety be insisted on. Children love to sing, and every harmless natural impulse should be fully utilized. There is an enormous moral value for young people in everything that illustrates the power of cooperation.

A few good voices will carry along with them the feeble, inaccurate ones. The total volume is inspiring. Each feels that he has contributed something toward the pleasurable result. Furthermore, singing has great value as a health measure because it requires expansion of the lungs. Children love to romp and play, but some of them need to be taught to play right; to breathe through their noses. When they do not do this there is an obstruction. It should be corrected before the consequences to cranium and ear become serious. Defects of bony and muscular structures should be discovered in kindergarten and primary school, because when found early many of them can be corrected.

The teaching of physiology and hygiene to the youngest pupils requires no book, but it does require a trained teacher. Unfortunately, however, there are teachers who do not care for that feature of the work even though they are competent. The reason for their indifference to the subject is that they did not grow up in that atmosphere of health culture which I would like to see created for the next generation. Some teachers prefer telling and reading fairy stories, and a little of that is good; but we have too much of it. The young pupil grows to demand entertainment and then to resent any call on him for serious work. Pleasure in work is an undoubted aid to concentration, and hence, if, in the instruction of a child, we can in some measure coincide with natural bent and inclination for certain studies, there is great gain; but this is essentially different from attempting to conduct education as a holiday excursion up the steep slopes of Parnassus, a journey which still has to be made on foot and involves for rich and poor in worldly goods or mental attributes no small privation and effort. Pleasure in work should be the aid, not the object.

The really clever teacher makes his subject entertaining and interesting but does not wander far afield in search of mere diversion. The teaching of health and the first anatomy and physiology lessons will be by the Socratic method of question and answer, and by the still older case-method first known as the parable. There will be no fear of lack of interest when the day's session begins with a tale like this: "John ran away from his mother. He was so little and he ran so fast that he fell down. There was a piece of glass just where he fell and he struck the sharp edge of it with his hand. What happened? What made the blood come? What is blood? Do animals have blood? What is it for? How was the bleeding stopped?" Such lessons can be varied and multiplied indefinitely and made practical by reference to or, when possible, by actual demonstration with natural objects and natural phenomena.

They are very much mistaken who tell you that children cannot think and would have early instruction rely in the main on memory. Even very young children do far more thinking and think far more accurately than the average adult realizes. They are not capable of abstract thought; but in relation to the things of everyday life they are constantly observing and trying to deduce conclusions.

The child is forever discovering new and surprising aspects of his terrestrial environment and is eager to investigate them. He gets into many a scrape through ceaseless experiment with cause and effect. He is eternally asking, "Why?" What a field is this young mind for the sowing of seed, and how much needless

suffering and disappointment he can be spared if we will only teach him the important things first.

In the kindergarten and in the lower grades of the primary school which are to be devoted, in the proposed scheme, to health and hygiene, clean hands, clean finger nails, clean faces, proper carriage, proper breathing; sound, well-brushed teeth, and all the little details of physical deportment that are matters both of social convention and of health (like the use of a handkerchief for a moist nostril, holding up the hand to cover the sneeze or cough) will receive reward and make for class standing exactly as does the correct solution of an algebra problem or a good recitation in the higher grades. As the pupil grows and advances, the health instruction will be increased and extended, and will, I am sure, serve to make chemistry, physics and natural history more interesting in themselves, while, conversely, these topics will render more intelligible the hygienic lessons.

PUBLIC SCHOOLS AS NATURAL HEALTH CENTERS

Our public schools, then, must become the health centers of their respective communities. Every measure carried out in them should be fully explained, so that the wisdom of preventive measures shall be fully appreciated by the pupil and he may become an advocate of them for the rest of his life. Will not the children who have been cured of hookworm and its attendant anemia, and come to feel the joy of physical and mental vigor for play and for work; be lifelong converts to health propaganda, and will they not be deeply interested when the cause of their previous disability and its cure is explained?

In connection with the bowl of hot broth furnished daily there may be lessons in diet. Temperance in all details of food and drink may be inculcated at the same time that the evils of alcohol, tobacco and narcotic drugs are set forth. Then the necessity for scalding knives, forks and spoons must be emphasized and the menace of the mouth secretions fully explained. The child must acquire, on the grounds of health, the same horror of the mouth secretions that refined people have for the spitting habit.

Such a program may commend itself to you, but the difficulties attending its execution are rather staggering. In the first place, we must have better teachers, and that means teachers who have had special training and will therefore expect better pay. There will be need for special textbooks, and this is one of the most critical features of the whole business; for good books of any kind for children's use, and especially textbooks, are among the hardest things in the world to produce. A mere rehashing and boiling down of an advanced treatise will not meet the requirements at all. We must captivate the imagination. We must arouse and hold interest in the topic discussed; we must stimulate thought, avoid overtaxing the memory and teach only facts which are scientifically sound, however simple the presentation. Now we have men and women perfectly capable of handling hygiene, physiology and physics in the proper way, but publishers are slow to take up new lines until they are convinced that there is a demand justifying the expense of an edition; and so long as such a movement as this is begun in a small tentative way and as a local experiment, publishers will hesitate.

While on the subject of schoolbooks, and having in mind the examinations conducted under the draft law,

which revealed a high percentage of refractive errors in our adult population, I cannot refrain from making something more than a passing comment on the type used in the schoolbooks supplied to young children. Some thought has been given to schoolroom illumination and to proper posture in reading, but nine children out of ten, if left to themselves, get their noses on the paper when they write; hold the book too close when they read, and will do both without regard to the quantity or source or direction of the light. Dr. G. I. Hogue, in an address before the schoolteachers of Milwaukee, estimated that 30 per cent. of the schoolchildren of this country had some visual defect. In Milwaukee, 27.24 per cent. of the schoolchildren had visual defects. In New York City, out of 650,000 children in the public schools, 30 per cent. at least were two grades behind what they should have attained. Ninety per cent. of these backward pupils are suffering from some defect in eye, ear, nose or throat. He estimates that out of 22,000,000 schoolchildren in the United States, some 6,000,000 suffer from ocular trouble. Good food, ample exercise in the fresh air, and hygienic surroundings will counterbalance a host of objectionable practices; but the ever-growing strain imposed on the human eye by modern life calls for special consideration. I profess no special knowledge of the pathology of the eye, and I have consulted no specialist preliminary to making these remarks; but I do not hesitate to declare that the time is ripe for a reform in the construction of children's schoolbooks.

CAUSES OF EYE STRAIN IN CHILDREN

When you get home from this meeting take your child's geography, history or arithmetic—if not blessed with a child of your own, a nephew, a niece, a neighbor's or a patient's child can supply you—and observe what a large proportion of the text is in fine print. The paper is good; the illustrations are attractive, and the binding is child-proof; but the questions for review, the footnotes, and much of the explanatory matter are set up in six point. I think I am very conservative in the opinion that no child of 10 or under should have to study a book printed in anything smaller than twelve point lower case or eight point capitals, and older children should not have to con by the hour a type finer than ten point. If fine print could be officially stigmatized as a menace to eyesight; if the federal government were to forbid the transmission through the mails of children's schoolbooks improperly printed, we would have a ready solution of the problem. Left to the example of the individual school or to the individual state, the correction of an evil of this kind will not be achieved for many, many years.

This thought and a consideration of the difficulty of securing the services of properly trained teachers and sanitary inspectors and physicians not merely for local experiment, for the collection of data, as a demonstration of some useful doctrine, but as part of a continuous and permanent health campaign, lead naturally to a consideration of government responsibility for the public health fostered and encouraged in the children but affecting also the adult in relation to trade and commerce, preparation for war and so on.

I wish that the public had a fuller appreciation of the really great educational work of our distinctly military services. Through the work of the medical officers of the Army and Navy, our government may be

said to have been carrying on for years a health propaganda, within the sphere of the activities presided over by two cabinet officers, affecting directly some 200,000 men in time of peace, and, to a much more limited extent of course, in the past three years acting on a force of several million men. But if we continued to maintain an army of from two to three hundred thousand men and a navy of a hundred thousand, the matters of health which are made prominent in military service would still not directly touch half of 1 per cent. of our population, and we have these men under our influence for relatively short periods—not more than from four to eight years out of a life of three score. This humanitarian, educational work is an incident and not the chief purpose of the departments referred to.

We have to admit, then, that vital as it is for us to maintain a high standard of physical development for the eventualities of war, neither the Secretary of War nor the Secretary of the Navy has any way of concerting measures which will assure for the military needs of the country the necessary number of men of sound bodies with unimpaired special senses. We reject every year thousands of applicants for enlistment who are ineligible for service by reason of conditions which might be regarded as preventable but which are not prevented. We reject men with serious defects of the teeth, with inferior vision or color perception, insufficient development of muscle, bone and tendon, poor heart-action and a defective innervation. Furthermore, the conditions of life in this hurried age; the social environment of the tenement; insufficient training in the home or the lack of a home, and the ravages of alcohol and syphilis in parents, are making for the development of neurotic and unstable types unavailable for service training in peace and of worse than no value for war. All these men are debarred at the recruiting office, but what becomes of them? The Secretary of War and the Secretary of the Navy have no cognizance of them, but they remain a part of the nation, an element of weakness, a burden, a disgrace, and transmit their defects and weakness to their children. The bad teeth; the weak, strained eyes; the overworked, injudiciously used hearts, and the distorted and depraved nervous systems are all preventable. Whose care is it to concert far-reaching plans to fend off from the younger generation and future generations ills that are not by any means an inevitable concomitant of birth?

NEED OF A FEDERAL DEPARTMENT OF HEALTH

Besides those specifically charged with the defense of the country, we have eight other presidential advisers or cabinet officers, each at the head of an extensive establishment and, together, they are supposed to have a supervisory action in regard to the great fundamental needs of the nation; and yet no one of them is specifically charged with the care of the nation's health. Neither the Department of the Interior nor the Department of Labor takes health into account on any considerable scale. It is by what might be called an accident of birth that our very efficient but small Public Health Service is conducted by the Treasury Department.

The U. S. Public Health Service, originally called the U. S. Marine Hospital Service, dates from 1798, when Congress made provision for the medical care of sailors in our merchant marine by generously mulct-

ing each sailor 20 cents of his monthly pay for the support of hospitals ashore and for the pay of the physicians who worked in them. The money was to be collected by the several collectors of customs, who were of course officials of the Treasury Department. It was not until nearly a hundred years later that this body of physicians had any but a curative function.

In 1878 Congress directed the supervising surgeon to prepare and forward to state and municipal health authorities weekly abstracts of consular reports and other information relating to contagious and epidemic diseases; but it is interesting to note that even in 1796 Congress had recognized some measure of responsibility for public health by passing an act requiring all revenue officers to cooperate in the execution of state health laws.

In 1879 Congress appropriated \$50,000 for a National Board of Health, whose existence was limited to a period of four years. This board owed its creation to the terrible epidemic of yellow fever raging in the Mississippi Valley. It was after this that the Marine Hospital Service was financed by funds voted by Congress for the specific purpose of preventing the spread of epidemic disease, more particularly smallpox and yellow fever.

In 1892 the Marine Hospital Service achieved notable results in preventing the introduction into this country of the cholera so extensively prevalent in Europe. Then came the passage of an interstate quarantine law and later a national quarantine act in virtue of which a systematic examination of all immigrants has since been maintained. Gradually this service has assumed a distinctly educational function. Its research laboratory was one of the first agencies of the kind. Its work in connection with malaria, pellagra, hookworm, infantile paralysis, leprosy, rabies, typhoid and Rocky Mountain fever, school hygiene, the pollution of water, trachoma, the problems of rural life, and railroad and industrial sanitation, has been of a high order.

I give this outline of the history of the United States Public Health Service because I think too little is known of what it has accomplished; because its growth in importance shows very plainly that, as the value of this kind of work became more and more apparent, ways and means were found to make it possible. The work has been economically done by trained experts often opposed by local prejudice but far more seriously hampered by general indifference and by the fact that they could act only in an advisory capacity, and were only a side issue in the Treasury Department, whose main concern was with other and very unrelated affairs.

This history of the Public Health Service illustrates how the government has been able to play a rôle of considerable importance in promoting public health though acting in an ancillary capacity, and we see how from purely medical practice its members have assumed more and more an educational function. Then, too, in recent years the government's obligations have been recognized by the passage of pure-food and child-labor laws; by enactments regarding the sale of narcotic drugs; by assigning to the Public Health Service supervision of the manufacture and sale of serums and vaccines. But today the public health is, so far as the federal government is concerned, a matter of secondary importance, whereas it should be first.

WASTAGE OF LIFE AND NATURAL RESOURCES

As a people we are of all civilized nations the most wasteful of human life as well as of food, natural resources and public funds. France and Italy have a minister of public education, and England has a ministry of health. During the year 1917 our railroads, which under government administration cost us a million dollars a day, were responsible for 194,000 injuries, 6,300 of which resulted in more or less serious crippling, and for 10,000 deaths. In the same year the funds assigned for the maintenance of the U. S. Public Health Service, including its laboratory, its department of zoology, its field work, the salaries of 200 medical officers and 1,800 other employees totaled \$3,250,000. That is to say, the national government's expenditure for its only accredited and official agency for the care of the national health was at the rate of a little over 3 cents a head for the total population. As regards vital statistics, birth registration and morbidity reports we are far behind Europe.

Doubtless the size of the land in which we dwell and the large population account somewhat for our laxness in these things, and of course the nature of our political organization does not make for a uniform and general plan of endeavor to increase physical endurance and physical capacity for output. Absorption in local needs and exaggerated or misconceived ideas of local rights bring a forgetfulness of the interdependence of these states and of the universality of public health interests. How often it happens that the least salubrious section of a state becomes the least populous, though its forests or mines or water power entitle it to be the most thickly settled. If sparsely inhabited, it of course has scant funds for ditching and draining, wholesale eradication of mosquitoes, adequate water supply or whatever the remedy may be. Under federal administration the greatest need would constitute the greatest justification for reclamation, and help would be more generally and systematically extended to counties and states which could not afford to remedy expensive local defects.

A department of health in Washington would be purely civilian in composition and would call to its aid or give its assistance to all private or corporate forms of endeavor, very much as the Army and Navy call on the Carnegie Foundation, the Rockefeller Institute or the American Red Cross. Then we would coordinate effort for improved public health of every kind and make it continuous and progressive instead of desultory and sporadic, and many problems would be diligently attacked which now, in spite of their importance, must wait until some great calamity excites public attention or arouses the sympathy of a philanthropist.

FACTS REVEALED BY THE OPERATION OF THE DRAFT LAW

We have learned and the general public has learned a good deal about our national weakness from the facts revealed by the operations of the draft law. Massachusetts, stimulated by the knowledge of the number and character of the rejections for military service, and other sections of the country alive to the declining birth rate of the white race are proposing enactments to remedy crying evils in the physical development of our people; but years may pass before other sections awake to the importance of these efforts. Mean-

while the whole nation is concerned, and the nation as a whole should be at work to remedy what is wrong.

If Massachusetts or Louisiana were to conclude that fine print and footnotes in children's textbooks were producing eye strain in the pupils of the primary classes in its public schools, and passed laws forbidding the use of a book in any of their public schools unless the type was of an ordained and specified size, this would be fine for the children of those two states. If, again, these sections of the country took steps to improve the general physical development of the young, this would be commendable and useful; but to what extent could Massachusetts or Louisiana supply the needs of the country in time of war? There is much to be learned from war, hard and cruel lesson though it be. As a nation shows itself in war so it is in peace. There is in war a test of the nation's capacity for the tasks of peace. War disrobes us of the figments of conceit and fancy, of self-satisfaction and egotism, and leaves us naked before the mirror of truth. The World War has been a liberal education to some of us. It should be used as a means of enlightenment to everybody.

How are we to explain the fact that the older sections, such as New England, New York, Virginia, North Carolina and Louisiana, lead in nervous and mental disorders; that in defects of the eye New York, Boston, and New England generally and the cities of Ohio, Michigan and Illinois were the most conspicuous; that Rhode Island led in defect rate and Vermont came next, while Kansas had the lowest defect rate of all the states; that the extreme northeast, including New York and New Jersey, made the poorest showing in regard to the teeth? Are these fortuitous facts or are they susceptible of explanation and correction? It is clear that when we have as physicians informed ourselves on these topics there must be education of the public to prepare it to cooperate with, and there must be legislation to enforce, the necessary corrective measures.

There is a mystery in the report of the Provost Marshal General that Oklahoma and Arkansas for the number of men examined gave the highest percentage of men going into Class A, and Arizona and Rhode Island the lowest—men in Class A being the fully qualified, able to see and hear well, able to transport themselves by walking, having a circulatory apparatus able to stand the stress of physical exertion, the intelligence to understand and execute military maneuvers, obey commands and protect themselves.

NATION-WIDE VERSUS STATE CONTROL OF HEALTH MATTERS

How unpractical to expect that any one state alone, or even two or three, should go into the study of these things at considerable expense, or that just and reliable conclusions could be arrived at from such a partial study! These are national matters most easily, most economically and most satisfactorily studied as national questions by national rather than local agencies. Not for a moment do I undervalue the investigations carried on by benevolent and scientific societies or corporations. One would have to be profoundly ignorant, deeply prejudiced, singularly ungrateful, to do so. Such enterprises excite discussion and help to create public opinion; but how slow is the general advance, how lacking in uniformity and concentration are the efforts of individuals and societies working in the

interests of a hundred million people! In America we are too prone to leave general measures for general betterment to professed philanthropists; and here as elsewhere what is everybody's business is nobody's business. There is a supineness, an inertia, a criminal neglect in the nation which surrenders to private agencies matters which are of vital concern to the development and expansion of the race and to its triumph in peace or war. Shall we be content to rely on the public spirit of liberal and enlightened millionaires, of a Carnegie or Rockefeller, to do for us, with all our boasted wealth and civilization, things which smaller and less rich nations regard as essential obligations of the governments they maintain and support; and is it not a devitalizing, corrupting, enervating, in every way demoralizing influence in our national life to trust for essentials of national happiness and success to what we must admit are accidental agencies?

I can perfectly understand a strong disinclination to any step that might appear to open the way for government control or restriction of the practice of medicine or that tended to paternalism, especially in view of the agitation developing here and there for all sorts of medical, dispensary and hospital privileges. On the other hand, history teaches that when in the complexities of modern life radical tendencies assume such force as to result in insistent demands for unusual and excessive privileges, it is easier to anticipate and circumvent than to overthrow them in open conflict. History teaches also that greed and violence are usually the result of previous injustice or neglect. There are no fortuitous happenings in nature. The geologists have long since ceased to talk of catastrophism; the physicists and chemists no longer recognize spontaneous combustion, nor do the biologists admit spontaneous generation. In the same way the convulsions of society always have a definite cause, although it may be deeply hidden. Whenever the superior intelligence and education of a given time or locality are threatened with overthrow by the force of an unreasoning mass, we may be sure that there has been neglect on the part of the superior or better favored to discharge its obligations to the inferior or less favored element. If as a nation we are lacking in all the proper provisions for promoting health and longevity; if the physicians who know about these things ignore their obligation to agitate in the matter and obtain results on legitimate lines; if everything that we consider needful to health in connection with industries, public carriers, charities, and the like is not done according to the means and the light we possess, we may be sure that sooner or later a wave of protest and clamor will sweep over the nation and that we physicians, along with other members of the educated classes, will have to pay an excessive price for previous passivity and indifference.

As a general proposition, I am firmly opposed to the disposition to saddle every public and semipublic enterprise on the government, a tendency arising from a profound misconception of government and its legitimate function, and often associated with a disinclination on the part of those displaying it to perform their own individual duty. But I am unqualifiedly in favor of a national department of health with a cabinet officer at its head which shall by its very creation give a great object lesson to our people and shall correlate and vastly expand all the efforts now put forth for the improvement of the race, the prolonging of life and the full development of physical capacity for work and

production. By reason of what it has accomplished in the past and because of the incalculable volume of influence which its individual members can exert in the various communities where they labor, I believe this this Association can effect this legitimate enlargement of government effort as soon as it sets to work whole-heartedly to do so.

I have drawn your attention to the vast latent possibilities for health propaganda in the public schools. I have tried to show that the nation's health, being a vital national concern, should be the particular care of a department of government on a par with the importance, dignity and power of existing departments which affect commerce, labor, revenue, agriculture, the mails and military preparedness; that popular government cannot ignore the human element, the physical element in the people. Permit me now to advert briefly to the practice of medicine as bearing on general scholastic training.

In the main, the medical curriculum of our leading colleges seems satisfactory, judged by the results. There are two points, however, which I do wish to mention briefly. In a recent able and discriminating paper, Dr. Hobart A. Hare of Philadelphia has brought out the well recognized fact that all recent graduates and many old practitioners are profoundly ignorant of drugs and how to prescribe them so as to get the desired results, and he has made an extremely important distinction between the invaluable researches of the scientific pharmacologist on the one hand and the teaching of practical therapeutics on the other. The medical student has no need, as an undergraduate, to engage in experimental work; but he should be taught what and how to prescribe, and to this end should have a short, simple course in practical pharmacy and a very thorough course in applied therapeutics.

In the second place I beg to submit that hygiene and sanitation are not given sufficient prominence in our medical courses. This is amply proved by the poor showing made in these subjects by the candidates appearing before the National Board of Medical Examiners. These topics should receive special emphasis, and the candidate for a diploma must be made to realize that competence in surgery, obstetrics or bacteriology will not atone for deficiency in a branch which, while not by any means fully setting forth the modern conception of medicine as a profession dealing with people collectively, socially and industrially, at least paves the way for a grasp of that conception.

For the medical school to provide a few lectures on hygiene is not enough. The school which does no more than this is not alive to the call of the twentieth century, which demands through the voice of rich and poor, of high and low, better living conditions for the world. We are tempted sometimes to berate the public for its indifference to health and its callousness to the wise injunctions of medical writers and speakers concerned with prolonging life by care of the body; but is not the public bound in such a matter to be behind the professed master, and are we not as the whole rather sunk in crass indifference? How many capable practitioners are really in a position to give sound, scientific advice on the thousand and one details bearing on the preservation of health derived from a knowledge of hygiene in any way comparable to the knowledge they are bound to possess in a score of other things if they are really the kind of physicians they ought to be?

Is not our profession constantly brought into discredit by the ignorance of the family physician and of the eminent specialist about matters of real and vital interest to the general public?

PRACTICAL KNOWLEDGE OF HYGIENE NEEDED BY PHYSICIANS

Our semiscientific and popular current literature, and even the daily papers, are constantly giving out bits of information about the flea, the louse, the bedbug and the mosquito in their relation to the transmission of disease. A layman does not quiz his physician about anatomy or pathology, but he does turn to him for enlightenment about these and kindred matters bearing on health and disease which he can understand and on which he would like to be informed. When the physician cannot fully satisfy the questioner about the rôle of these insects; about the potability of water; the danger of damp, newly constructed buildings; the proper trap to a water closet, and the infections that may be acquired from intimate contact with domestic animals, he loses enormously in prestige and, what is more important, he loses the chance to thrust home some valuable lesson in public health and public duty.

We are beginning to develop here and there schools offering special courses and special degrees in hygiene, and I think this is a forward step, for we must have men of special training prepared to do advanced research work in this field; but can any one reasonably pretend that the medical profession can wisely permit this branch to become one for specialists only, and that, while pathology belongs to the physician, hygiene and sanitation are not his sphere? On the contrary, will not the exhaustive teaching of hygiene and of public health medicine in our medical schools immeasurably enlarge the scope and improve the character of the practice of medicine itself?

Let us institute a thorough course in hygiene and sanitation, making a real knowledge of the subject indispensable for graduation. We could include in this course whatever features of the specialties bear directly on the public health.

RESTRICTIONS AS APPLIED TO CANDIDATES FOR ADMISSION TO MEDICAL SCHOOLS

Far more important than determining what particular subjects are to be emphasized and how the medical student's time is to be apportioned in classroom and laboratory is the standard of fitness to which a young man must conform before he can be permitted to study medicine. Admission to a medical school contains the implied promise that diligent application for a given period will qualify him for a diploma as a doctor of medicine. In justice to the public, to the profession, and to the candidate we must endeavor to establish three things before the medical school opens its doors to him. The prospective physician must be sound in body; he must have sufficient mental training and acquisitions to enable him to pursue the course with profit; he must give evidence of those personal, temperamental and moral qualities which promise reasonable adaptation to the highest aims and purposes and to the best practice of the American profession.

The first step in establishing the standard for admission to a profession is of course to define the scope of that profession. The distinction between medicine as an unlimited science and medicine as an art, more limited in scope and confined to a comparatively nar-

row field, was alluded to in these words by Huxley: "It is so difficult to think of medicine otherwise than as something which is necessarily connected with curative treatment that we are apt to forget that there must be and is such a thing as pure science of medicine." I have this distinction in mind when I urge that we shall not so arrange our scheme of medical instruction as to make it lean unduly to fitting men only for the practical curative art biased by the American inclination to demand immediate and practical results in a business and financial way. Some of our graduates will infallibly prove by temperament ill adapted to private practice; and if they have had during their student days no vision of medicine, no introduction to it as a science, they will drift out of medicine entirely. If our schools are wholly planned with the idea of turning out only men who can at once become practical bedside clinicians, do we not to some extent limit the chances of our country's taking a prominent part in the further development of the science of medicine? It is this fear which makes me feel that there is a place in our medical faculties for teachers of certain scientific branches even though they are not themselves practitioners. It behooves us to have close affiliations with the pioneers, and as Maeterlinck has well said: "We must beware of abandoning ourselves unreservedly to the prevailing truths of our time."

The distinction between the science and the art of medicine is a vital one. In the program of our medical instruction we must recognize that these two aspects of medicine exist, and we should provide instruction that will make it possible for graduates to be scientific and practical healers of disease or to develop as purely scientific investigators.

People have been inclined in the past to consider the clergyman and the churchman dogmatic; but dogmatism is also the besetting sin of medical centers, medical schools and practicing physicians. We may not be able to prevent individual practitioners from being narrow and prejudiced in their old age, but we can at least start our young men off in their professional career with a strong impulse toward liberality of judgment and breadth of view.

There is, I am convinced, a real danger in the modern trend to practical instruction so called. The danger of neglecting the necessary fundamental and more or less abstract teaching for the distinctly enjoyable clinical and bedside work is increased by the realization that the latter has stronger attractions for the student and that it greatly facilitates the acquisition and retention of information furnished in the classroom. Students and even teachers speak of schools as theoretical and practical, having in mind apparently the distinction between didactic lectures and laboratory exercises; but it is very easy for an unconscious transposition of ideas to lead one to think of theoretical instruction as removed from the domain of usefulness to the sick because the word theoretical is connected with the idea of speculation and hypothesis. Now, as a matter of fact, by theoretical instruction in medicine we mean the abstract handling and presentation of scientific truth as compared with its application as a practical means of healing. With this clarification of terms it becomes manifest at once that the school must be primarily the place for medicine as a science; for if the young physician have not scientific knowledge, what is he to apply when he comes to the bedside?

ERAS OF MEDICAL TEACHING

We have known in this country the era of strictly practical medical teaching. The physician jogged along from house to house, and the neophyte who accompanied him saw the patients and picked up what he could about them through the dissertations of the preceptor. It was followed by the era of cheap medical schools where men were shown at clinics the manifestations of disease: where they committed to memory prescriptions for fever or diarrhea or cough. These schools had short courses, and the fees for diplomas were essential to their maintenance. We have, through the American Medical Association, rung the death knell of the medical diploma mill. But historical justice compels us to admit that there was much excuse, in our country's undeveloped period, for giving some kind of brevet to men willing to settle and supply what primitive rude aid they could in remote and sparsely settled sections that would never have attracted or adequately compensated those who had spent the time and money necessary for more complete training in the half dozen high-grade medical schools we possessed. Conditions are very different now; there is a more equal distribution of wealth and education throughout the land; standards and requirements of various geographic sections are more uniform.

Now let us not be led astray by the insistent demand that our improved schools shall turn out men able from the start to display a high degree of curative skill, for then we shall unconsciously develop a type of school that for our times and standards is little more than a glorified elaboration of the narrow, superficial institution of an earlier day. Let us teach the science of medicine as far as we know it and superimpose on and combine with that, regardless of time and cost, the art of applying it. Let us not be afraid to weed out those candidates for admission to the schools who have neither the acquisitive nor constructive faculties which give promise of development. Let us be primarily concerned with what our graduates will do for American patients and American advance in medicine five and ten years after graduation.

I look forward to the time when we shall have in this country an even higher standard than now and uniform medical requirements with comprehensive courses of five and six years as in England, France and Italy. The small, ambitious and ill financed private medical schools of the past have made impossible for us the practice of giving medical degrees of different values representing different degrees of preparation such as prevails abroad, because no school could expect to attract students if it conferred a degree less pretentious than that of the others. That a need for something of this kind has been recognized by the profession in this country is shown by the rise of the American College of Surgeons and other American colleges, to be a fellow of which implies an advance in attainments beyond those of the ordinary graduate. This need is shown, too, by the existence today of the National Board of Medical Examiners, an incorporated but privately supported organization whose aim is to stamp the successful candidates coming before it as men of peculiarly liberal acquirements.

The gradual elevation of state requirements for license to practice and their constant approach to uniformity justify this board in looking forward to a time in the near future when we shall have a single standard for the whole country; when men who have by their

actual work confirmed the justice of their title to practice in one locality shall not be under the painful necessity of undergoing examinations afresh if questions of health, family, finance, research or specialization lead them to remove to another section; when we can as a nation have proper reciprocal medical relations with the great educational centers and the licensing bodies of Europe. It is in view of all this and because of the need of a good deal of reform in our actual conduct of examinations that the National Board of Medical Examiners was organized. It is in pursuance of our desire to secure from Europe proper recognition of American progress in medical education, to tighten the bonds which unite us with our foreign brethren and to enable us to profit by their greater experience that this board invited to America as its guests the following distinguished gentlemen: Sir Humphrey Rolleston, K. C. B., of the Royal College of Physicians; Col. H. J. Waring, Fellow of the Royal College of Surgeons; Dr. Norman Walker of Edinburgh, and Professors Grégoire and Roussy of the Faculty of Medicine of the University of Paris.

In practice and in our preparation for practice we swing pendulum-like from extreme to extreme, and it would almost seem as if real activity, earnestness and conviction are radical and exaggerated, and that inevitably the effort to moderation and a rational conservatism involves inaction.

Galen in trying to stabilize medicine, to free it from wild speculation and the vagaries of individual schools and the excesses of individual teachers, bound it with iron bands and stopped all progress for thirteen hundred years. The Faculty of Paris, standing like a rock for a maximum of book learning, insisting that the physician must be a savant, holding to narrow conceptions of the dignity of the profession, despised the manual operations of surgery, exacted from aspirants for a license an oath to do no surgery, and by cutting itself off from the opportunities for acquiring that knowledge of anatomy, physiology and pathology afforded by operative investigation made the practice of medicine in France as dead and as meaningless as the branch which it so effectively circumscribed for four centuries. But just here is a feature of the development of medicine that we are apt to overlook. It was not until the itinerant bone setters, the cutters for stone, the oculists, the herniotomists succeeded in being admitted to the schools that they exercised any vital effect on the profession. The schoolmen were narrow, as every one admits, but the practical men who had not been to school were butchers, and they had no real influence until surgery in the person of Felix cured Louis XIV of a fistula in ano which had never been benefited by salve or unguent. Maréchal, successor of Felix as court surgeon, influenced Louis XV to establish five chairs of surgical instruction, and La Peyronie induced him to pass an ordinance making it obligatory for masters of surgery to qualify first as masters of art.

THE EVILS OF TOO PURELY ACADEMIC INSTRUCTION

In recent years we have perceived with ever increasing intensity the evils of a too purely academic instruction, and in the inevitable reaction to practical methods we run the risk of going to an equally dangerous extreme the other way. It behooves us to find a way to teach so that the two lines shall have their proper proportion.

The Renaissance, which introduced a deeper and wider study of the classics, was at the same time the period of humanism, a term I like because it suggests in itself how with the revolt against dogma came a fuller recognition of the human side of life; of the rights, the claims, the needs of the individual and an increasingly general recognition of the fact that the study of mankind is man. The Renaissance marked also what may be called the resurrection of the human body from the grave of ignominy and contempt into which it had been cast by the early Christian and medieval church in its fight against the lusts of the flesh.

Through the stretch of the centuries men have sought in vain the anatomic seat of the soul. Samuel Johnson aptly remarked that "all power of fancy over reason is a degree of insanity." We waste no time today trying to locate the soul in pituitary body or pineal gland, and we insist that physical findings are the basis of diagnosis and treatment; but the physician's preliminary education must take into account the sentimental and imaginative side of life. What true and worthy practitioner fails to feel the appeal of the soul in the searching look, fastened on him as he enters the sickroom? The physician's principal function, as in the days of Hippocrates, is still to assist the healing power of nature. We know that with all our science much of our medicine is without efficacy so far as its direct ostensible purpose is concerned. The doctor's personality, his power to inspire hope and confidence, his understanding of human conduct, his analysis of character remain his chief asset at the bedside. All ages, whatever the attainments of science, have produced great healers, and the family physician of an earlier generation with his kindly sympathy, his unselfish devotion, his capacity for toil and vigils must ever remain the ideal minister to the sick. It is the personality of the upright, big-hearted man whom people trust to use what knowledge he possesses rather than abstract scientific qualifications that counts in the long run. Can we expect men to qualify for the sacred function of receiving the confidences of sufferers in mind and body if we expunge poetry and philosophy and art from their preliminary education and wholly replace fairy tale and legend, Longfellow, Tennyson, Hawthorne and Shakespeare by so-called strictly scientific premedical work? We want a man broad in interests and understanding, not the recluse who finds more pleasure in dissecting a beetle than in viewing a sunset, who gets more soul satisfaction out of the hum of a machine just because it is a machine than in listening to a Patti singing the Last Rose of Summer. Dr. W. M. Beach of Pittsburgh well epitomized all this when he said at Atlantic City last year that "proficiency in the physician requires development in the direction of spirituality; there is a curative force that is moral."

THE KIND OF MEN NEEDED

We want the men who take up medicine in America to be big men; big in heart, big in brain, blessed with vigorous health. The possession of a store of facts is nothing as compared with evidence of native ability and sterling integrity of character. Before we permit a young man to matriculate in medicine we should have assurance that he is careful of his health and careful of his financial obligations; that he commands the respect of former classmates; that he has qualities that make for leadership: above all else that he understands and justly values and possesses that indefinable,

exquisite, delicate something as intangible but as real as the bloom on the plum and the fragrance of a wild flower—the sense of honor. Our inquiry into the pre-medical career of a prospective physician will be of infinitely more value if it enlightens us on these points than if it merely establishes his ability to memorize a book and on admission we discover that the high marks and the multiplicity of diplomas were won by a physical and moral runt. When our schools generally, as one or two now do, come to view the premedical standing as one to be deeply investigated and carefully passed on, we shall have fewer graduates, perhaps, but a relatively larger number of real physicians in whose ranks there will be no fee-splitters, no men of shady reputation and questionable conduct to disgrace us and forfeit our title to the confidence of fathers and mothers.

It is time that the subject of examinations be very thoroughly gone over by professional educators, and substitutes found for such methods of testing a candidate for promotion or honors as do not indicate reasonably lasting acquisition. The bulk of our examinations as at present conducted have but little to recommend them. Their only merit and the reason why the pedagogic world hesitates to discard them lie in the powerful stimulus they provide to the study of even the most difficult branches and the most obnoxious details. When, however, we stop to consider that the labor incited by examinations is usually not for the acquisition of knowledge but for the passing of the examination; when we admit that the modern examination determines, in the main, a very ephemeral form of attainment, we may find that something better than the examination may not be so very difficult of accomplishment after all.

PRESENT METHODS OF EXAMINATION

The present method is vicious for two reasons: First, it fails largely of its object because we do not get a correct idea of mental capacity and mental development, nor a proper appreciation of a student's grasp of the subject by examinations which he can undergo successfully by cramming. In the second place, cramming is a devitalizing process and the very opposite of memory cultivation, because behind the effort to acquire is the deliberate conscious purpose of unloading the mind of the stores taken aboard as soon as a given contingency has passed. The willingness to forget and the deliberate effort to forget negative and weaken the retentive power.

Memory is still an essential, but written examinations often demonstrate only that facile and superficial memory which picks up and carries for a while under stress of need very much as a stream in freshet carries down rocks and earth, dropping the heaviest first and bearing the sand even to its own finish in the ocean.

For years, in our examinations at the Naval Medical School in Washington, we have allowed laboratory notes to be used by candidates in the chemistry and hygiene laboratories, considering that memory for the exact quantities in various solutions is not required, nay, undesirable, where men are trying to do accurate work. What we demand are the principles involved, the meaning of the steps, the interpretation of the results. This is the method followed by the National Board of Medical Examiners. It is in the necropsy room; the laboratory and the hospital ward that we test the candidates in an endeavor to ascertain what they know by what they do, instead of judging entirely by what they say or write.

It is gratifying to observe that medical men are giving more and more thought to the subject of premedical education, and I consider this a most favorable augury for the future of American medicine. We may not yet be in absolute accord as to the means of obtaining the best type of medical student, but it is something to agree that we need in medicine the scientific investigator as well as the scientific practitioner, and that each is dependent on the other. We are agreed too that what we require in preparation for medicine is not scholarship but a process of training which shall develop a certain mental attitude as well as a certain degree of mental power. This unites us at once with the interests of the legal and other liberal professions, and a common platform as to our desires inevitably simplifies the problem of arranging a satisfactory high school course. If we wanted a strictly scientific course as a preparation for medical study we should be compelled to arrange for the paths of school and college education to diverge very early from those to be pursued by men looking to some other career; but I hope we realize today as never before that the true aim of preliminary education is not so much to fit men to study medicine or law or architecture as to help them achieve the fullest success in the pursuit of these several callings. If our primary requirement is for capable men, then we can combine with every other profession which is similarly more concerned with molding character and increasing the range of mental outlook than in making the final technical course easier by a preliminary one which invades the territory of the professional school.

BASIS FOR SCIENTIFIC STUDY

We must concede the soundness of the contention of Bain of Aberdeen that: "In a right view of scientific education the first principles . . . of all the great sciences are the proper basis of the complete and exhaustive study of any single science."

Sir George Makins, president of the Royal College of Physicians, does not think that we should relegate the teaching of physics, chemistry and biology to the premedical period for fear that the medical student may not have a sufficiently thorough grasp of these subjects. On the other hand, Thomas Huxley held very emphatically to an opposite opinion. He said: "The great step toward a thorough medical education is to insist on the teaching of the elements of the physical sciences in all schools, so that medical students shall not go up to the medical colleges utterly ignorant of that with which they have to deal; to insist on the elements of chemistry and the elements of physics being taught in our ordinary and common schools so that there shall be some preparation for the discipline of the medical colleges."

I agree with both Makins and Huxley. My own view is that these subjects should be taught in the school and college course and in the medical school also. In the preliminary courses, pupils should acquire a knowledge of the great fundamental principles involved and the methods employed in scientific work, because all this emphasizes the value of accurate observation and correct interpretation of facts, and both of these mental processes are invaluable in every department of human activity. The future lawyer, doctor, business man needs this training. In the medical school chemistry, physiology and biology will be taught with reference to their bearing on medicine. But the premedical courses must be very different from those now pursued. The textbooks must be simpler and the

courses be made general, and then pupils must be compelled to master what they go over. There is far too much superficial teaching, too much smattering of knowledge at present. This leads to nothing and negatives the very object in view. Huxley appreciated this and usually preferred to teach the beginners himself, so as to be sure that they started with a proper comprehension of the fundamentals, and he left to colleagues and advanced students the subsequent conduct of the classes.

I should put biology and physiology or nature lessons among the earliest, since they go naturally with the health teaching and the hygiene by which all schooling should begin. Next would come physics, which will be attractive to the great majority of active-minded youngsters who are animated by a desire to do things, to make things, to understand electrical devices, automobiles, telephones, flying machines and the like; but I would see to it that they did not waste their time in trifling manual accomplishments but were enabled to understand the principles involved—the development and transformation of energy, latent heat, expansion and contraction of gases and gravitation. Chemistry would come later still. The college course would permit a resumption of the physics and chemistry, at least for medical students, while others would elect something more distinctly related to the careers they planned to embrace.

It will be impossible, I fear, to allow for more than two years of college for the intending student of medicine with five years of classroom and practical work still ahead of him. We want him to graduate while relatively young so that he may face the discouragements and trials of early practice and the long uphill climb to a financial competency while still possessed of the resilience, the buoyancy, the freshness, the enthusiasm, the high courage and the endurance of youth.

In enumerating these so-called scientific features of premedical education it is important to remember that a slightly greater familiarity with them prior to matriculating in medicine will not compensate for the dwarfing effect of a course restricted to them and unbalanced by studies of a complementary character, bearing always in mind that the object of premedical work is to develop, not to indoctrinate. Bain has well said that "the defect of the practical man is the limitation of his tests to his own sphere of working; he seldom learns to extend his method into other spheres." Now the sciences have a definite place in all education quite apart from the direct acquisition of useful facts. Observation, analysis of evidence, accuracy of statement and definition, the insistence on proof and demonstration are among the features that render scientific studies so useful in themselves; but are we not guilty of unpardonable onesidedness if we let only the physical part of the animal man occupy our pupil's attention in our enthusiasm for nature study?

It is many years since Mr. T. Davison wrote these significant words: "A man who has been trained to think upon one subject, or for one subject only, will never be a good judge in that one; whereas the enlargement of his circle gives him increased knowledge and power in a rapidly increasing ratio. So much do ideas act not as solitary units but by grouping and combination; and so clearly do all the things that fall within the proper province of the same faculty of the mind intertwine with and support each other. Judgment lives, as it were, by comparison and discrimination."

MISTAKES OF THE MIDDLE AGES

Education, and as a part of it medical education, in the Middle Ages, was distinctly scientific in character. The strong literary bias and the study of languages which became so marked in the seventeenth and eighteenth centuries did not develop until the Reformation and after. This is not commonly appreciated, but it is a fact. Mathematics, astronomy, chemistry—or, if you choose, astrology and alchemy—and even metaphysics, grammar and rhetoric, as they were taught, were not literary studies but distinctly along the lines of scientific training. True, much of the science of the Middle Ages is held in contempt today; but science and its standards are forever changing, and we cannot require of educators that they shall teach the unknown but only that they shall be abreast of their times.

Now, then, when we consider that for 400 years the premedical studies of Europe were grammar, rhetoric and dialectic, making the trivium; and music, arithmetic, astronomy and geometry, making the quadrivium (called collectively the seven liberal arts but really sciences not arts), and when we realize how absolutely sterile of results was the medical practice to which these premedical studies lead up, have we not some basis in history for questioning the extreme ground which some people take today in decrying the value of the humanities and insisting on purely technical preliminaries?

The Hon. A. J. Balfour, an Eton and Cambridge man, author of the Education Bill, one of the early champions of the higher education of women, an earnest advocate of technical training and of every form of practical instruction which might enable the British man of business to hold his own with foreign competitors, epitomized his thoughts on education in a speech delivered in 1899 at the Ley School. He admitted that a few years of Latin and Greek study do not suffice to accomplish the intended purpose of introducing the scholar to the beauties of ancient literature in the original, but he did insist on the importance of some form of literary education, nay, regarded this as indispensable. I think the opinion of so versatile a man as Balfour, once a successful opponent of Gladstone, leader of the House of Commons, an uncompromising yet locally popular secretary for Ireland and the representative in Parliament for the laboring men of East Manchester, is well worth heeding.

THE PLACE OF LATIN AND GREEK

There is no question that we must give up Greek, and I believe that Homer, Sophocles and other ancient authors will give more pleasure through the good translation of ripe scholars than from the perspiring school-boy's own efforts; but I consider that Latin, if ably taught, has a place in our schools. I do not offer in support of this study that it helps in acquiring scientific nomenclature, for that is as roundabout and difficult a way of doing the thing as Charles Lamb's roasting of a pig by burning down the place of his abode. I believe in three or four years of Latin because, along with other and indirect benefits, it is the easiest and surest way of teaching boys and girls to write and speak English correctly. I cannot take the time to marshal the arguments for this contention. Suffice it to say that the elasticity and simplicity of our construction, the practical lack of declension and conjugation inherent in our language, as well as many features of American life and thought, combine to

make for careless and inaccurate writing and speaking. Latin is not an elastic, plastic vehicle of thought like Greek, English or French, but an inflexible one cast in an iron mold. Properly taught to young people of reasonable intelligence, the translation of Latin into English prose can be made as fascinating as a picture puzzle, once those forms have been mastered which are essential features of the organic structure of a sentence and give the clue to its meaning. The study of Latin is thus a powerful though indirect method and, because indirect, the easiest way of teaching English grammar. It should be begun early when the necessary memorizing will be least laborious, and continued beyond the time when the pupil would be put at English grammar, a study of great difficulty and universally obnoxious. Grammar can be taught, as it were, objectively and solely through Latin, which illustrates the rules of construction in a way that our own language does not.

NEED FOR MORE ATTENTION TO ENGLISH

And if I am right in this idea, I think the place of Latin is secure in the schools because the one thing that we must insist on is that our boys and girls, whatever their purpose and destiny in life, shall speak and write English correctly. Nowhere in the world is there such need for the teaching of the national language, because nowhere is the school population made up of such a variety of elements, and in the case of many their mother tongue is not English. With no pretension to a mastery of style and no great sympathy with the exaggerated purist, I am nevertheless frequently surprised by the laxness, the inaccuracy, the atrocious barbarisms of the language of daily conversation and even of the public press, the magazines and the books printed in this country. Long observation as examiner on Navy boards has brought me to a realization of the sad fact that the young men of America can go through the high school and even obtain a baccalaureate degree, and yet be incapable of writing plain and simple English correctly. In this respect I submit that we are behind our parents and grandparents. What would have been an occasion for mortification and reproof fifty years ago is today a jest, and our young people are permitted a slovenliness of expression which surely reflects a decay of standards in more ways than one, encourages mental laziness and must have a depreciating effect on *cerebration* itself.

It is to deem knowledge of little value and to take a narrow, selfish and limited view of intellectual pursuits of any kind to deliberately despise and neglect language, the instrument by which we contribute to others and make them sharers of our work and its results. The crying need of premedical scholastic training in America, and of all school and college training at the present time, is for reform in the teaching of English. By this is not meant that boys and girls must write in learned or stilted or flowery style. Nothing of the kind. But accuracy and clarity of expression are valuable for all and essential for the professional man.

With all due respect to our capable, earnest and largely underpaid teachers, I must confess to a feeling that our public school courses are suffering from too large a variety of subjects to permit thoroughness. This is serious, because it is not so much what is taught that counts, as the permanence of the knowledge and the effect on the acquisitive mechanism produced by the way study is conducted. A superficial acquaintance, a smattering, a glossing over of a thing is pernicious in the extreme. Better no schooling than such

a process. For some of this mistaken policy and for the idea that school must be a place of entertainment and amusement rather than of hard, grinding work, I hold the parents responsible. Too many of them, while contributing little enough toward education in the home, resent the pressure of the teacher and yet desire their children to leave the high school with a large variety of showy accomplishments.

What is put before the student of any age must demand effort; must consider what he may be able to attain by expansion and not what he starts with. For true progress education must be calculated not from the standard of averages either of ideals or capacity but with a conception of a maximum achievement and ability. It must give opportunity to all according to their talents but provide always for the development of future leaders and thus insure a gradual heightening of standards and conceptions.

As we contemplate the anomalous developments of the past year are we not bound to pause and consider whether we have not long been radically wrong in our whole system of education? The constant clamor of recent years to make education practical, to make the school courses adequate training for the real business of life may have arisen from a mistaken conception of what the real business of life is. Have we been a little hasty in assuming that poetry and philosophy, and much of what the thoughtlessness of American youth regards as old fashioned and useless, are not beneficial enough to justify the time they take from the supposed practical studies? Have we unconsciously been encouraging courses of study that breed only money-makers and worshipers of mammon? When our sons have been prepared for business and have made their money, and when our daughters have married men of wealth, the one thing needful, will it not be too late for them to acquire a taste for the highest and best things money can procure; can we expect that a love of beauty in nature and art will spring into being, that our children will have proper standards of beauty if the seeds for such tastes and such love were not sown in youth?

The true object of government, whether it be that of a state or of a university, is to broaden the vision of countless individuals as to the meaning of life, and to increase their capacity to add to the sum of human happiness, not only by some positive accomplishment, but by the development of those keen sympathies which recognize all that is good in others while supplementing their weaknesses and retrieving their failures.

Finally, we have to recognize that in every field of endeavor the best men are largely self-taught. In the progress toward the predestined goal disclosed by the lifting mirage of the future, each chooses his own path and has his own peculiar problems to solve. As he advances further and further into the kingdom of truth he discards authority and flings off the fetters of tradition. It is only the mediocre man satisfied with a stereotyped career that can be fully equipped by any system of schooling for all the eventualities of his small and narrow life. What the school and college can do for all is to develop the capacity for true feeling and sound thinking. The medical profession must agitate in season and out of season for a high standard of physical capacity as a basis for intellectual achievement and for normal conduct. It must show its full appreciation of proper values by using every means to divert from its ranks those who have failed to demonstrate the possession of principle as well as of mental proficiency.

SYPHILITIC SCARS OF THE SPIRIT

JOSEPH COLLINS, M.D.

NEW YORK

As one's experience with syphilis of the nervous system becomes more extensive, one becomes more deeply impressed with the fact that the literature of the subject lacks adequate statement or description of manifestations of such infection or of the results of it. Indeed, the mental scars of syphilis have had very scant attention from physicians. The various ways in which general paresis displays itself, the dementia of syphilitic encephalitis and the mental accompaniments of syphilitic endarteritis have been discussed and described, but the minor mental and emotional changes attending cerebral syphilis, and particularly those that are permanent sequelae of such disease that has gone on to recovery, have not been properly recorded. The reason for it is that they are so variable, they are so slight, and, perhaps I may add, so nonpathognomonic. However, they often succeed in thwarting the victim's career, reducing him from a man of promise or a man of accomplishment to a man of no importance or a dependent.

The clinical display of syphilis of the nervous system is very different today from what it was twenty-five years ago. Indeed, syphilis of the nervous system is today different from what it was ten years ago. This may be because the syphilitic virus is less virulent than it was in former times, but probably it is because the disease is diagnosed more frequently and earlier than it was and because it is treated properly and adequately. "Properly" means with mercury and arsphenamin, and "adequately" not only until all clinical manifestations have disappeared but until the Wassermann reaction of the serum has remained negative for a long time. It also means that the medical profession by and large has come to a deeper realization that potassium iodid is not an antisiphilitic agency in the true sense of the term, but a medicament that is of inestimable service in dissipating the products of cell proliferation due to syphilis.

Now that ten years have elapsed since I began the use of arsphenamin and mercury in the treatment of syphilis of the nervous system, I have had abundant opportunity to witness cessation of the progress of syphilitic nervous disease. In some instances, fortunately, this cessation has been accompanied with functional restoration to a degree that approximates normal. I have also encountered many cases in which the syphilitic disease was conquered by the combined resources of nature and of art, but in which the functional restoration was not complete. When such disease is of the intracranial contents, the symptoms are more conspicuous than when they are of the intraspinal contents. For instance, a tabes may be brought to a standstill, and the only evidence of the syphilitic scar is sexual impotence or slight impairment of vesical tonus. On the other hand, syphilitic meningo-encephalitis or syphilitic encephalitis may after recovery leave a scar which displays itself in altered behavior of the patient which is apparent only to those who come in intimate contact with him, in slight impairment of his intellectual and emotional capacity, which, although slight, is enough to shape his career, turning it from success to failure.

REPORT OF CASE

I have in mind the case of a young man of 26 who had made commendable progress in the mercantile world solely from his own effort and ability, and who was looked on by his friends as a man of promise. He left his house one morning of September, 1915, in apparently normal health. A half hour later he was brought home by a policeman and a stranger, who said they had found him lying in the street. He was not unconscious. He said he had been seized with sudden dizziness and had fallen. When he attempted to get up he was so giddy that he could neither preserve his station nor walk. For the next three days he complained in addition of nausea, and he frequently vomited. Gradually the dizziness disappeared, and at the end of two weeks he was able to sit up, and in four weeks he returned to his work. It was then noted that he was neither so alert nor so responsible as he formerly was, and he so failed to satisfy his employers that he was asked to absent himself from business and stay at home until he got well. From that time conspicuous mental symptoms developed. His family related that in addition to being drowsy and stupid, unresponsive and ambitionless, his behavior began to be very queer. He would drink while he was lying down, stuff his mouth full of food until he could not get any more in, attempt to swallow it without chewing it, urinate in his clothes, and throw his clothing or anything that he happened to pick up out of the window. In brief, his behavior was that of a man who had lost his mind. Unless he was specifically interrogated he made no complaint; then he would say that he felt "run-down" but that there was nothing else the matter with him.

The physician whose counsel was sought learned that he had married clandestinely six months before and that soon after that event his wife complained of a sore throat. When she went to a physician he diagnosed her disease as syphilis. Examination of the husband's blood revealed a ++++, Wassermann reaction, and he was put on mercurial treatment. He had received forty intramuscular injections when the symptoms that I relate developed. That is, he was under treatment when the first symptom indicative of meningeal involvement occurred. That symptom was paralysis of the facial nerve. Two months previous to the development of the symptoms noted, the right side of the face became immobile. It developed abruptly and involved all the branches of the nerve. After two or three weeks it gradually improved, but the remains of it were quite conspicuous when I first saw him. Six weeks after the attack of vertigo he made no complaint save that he was run-down. He admitted that he felt dizzy at times, but he had no headache, never saw double, and did not complain of stiff neck. He was inert, listless, unresponsive, neglectful of his appearance, and changed in manner and habit; but his conduct was no longer conspicuously bizarre. The only somatic signs of organic disorder of the nervous system were the residue of the facial paralysis, exaggeration of the tendon jerks, and an extensive, fanlike projection of all the toes when the sole of the foot was irritated. The Babinski great toe phenomenon was elicited on both sides, on the right more conspicuously and characteristically than on the left, and there was a right patellar and ankle clonus. His speech was somewhat indistinct and inebrious, and his answers were laconic; but there was nothing about his speech that suggested general paresis. His general appearance was that of a very ill man. He was emaciated and pale, and during the examination the skin was bathed in clammy perspiration. He weighed 98 pounds, his ordinary weight being 130. The laboratory tests were all corroborative of the diagnosis of basilar meningo-encephalitis, the spinal fluid containing about 150 cells. The following morning he was stuporous, and arousable with difficulty. When aroused he remained so only a moment, and then lapsed back into a condition as if he were overwhelmed by sleep. Indeed, his appearance and reaction were very much like a person in the beginning stupor of uremia or acidosis. Although he answered questions correctly, not infrequently he would stop in the middle of an answer and relapse into a stuporous state. He was able to get out of

bed unaided, to stand and to walk, but the latter was accomplished very insecurely. There was no trace of hemiplegia. The stuporous condition lasted about two weeks. At the end of that time he was confused as to time and place, and had practically no recollection of what had transpired from the time he entered the hospital. He gave a fairly comprehensive, sequential account of his illness up to that time. In reply to questions concerning his illness, he made the stereotyped reply, "Search me." However, he discussed the improvement that he had experienced, but without emotional accompaniment and without projection of plan or ambition. He read the papers and gave a fairly intelligent account of what he read, but he confined his attention to the comic sections and the sporting pages.

Gradually he began to display what might be called a triviality of conduct, a lack of responsibility, with no indication of gratitude for his recovery, no plans for the future, and no expression of desire to get home or to take up the activities of life again. After he had been under treatment for three weeks, during which time he had had two intravenous and two intraspinal injections of arsphenamin and daily mercurial inunctions, the Wassermann reactions of both the serum and the cerebrospinal fluid became negative, and the cells of the latter dropped to 11 per cubic millimeter. The only abnormality that it disclosed was slight globulin excess.

Gradually the patient's mental condition improved. He was no longer incontinent of urine or feces. He became more cognizant and observing of his surroundings; he took a keener interest in reading and diversion; he manifested more solicitude for the visits of his family, and displayed greater pleasure at such contact. His orientation of time and place became quite normal, his memory gradually improved, and his capacity for attention showed a greater awareness and retentiveness. He was neither depressed nor exalted, but displayed a general feeling tone that was not quite normal, though not particularly abnormal.

When he was taken into problems like mental arithmetic, in which he was formerly very alert, he became readily confused. His chief behavioristic phenomenon was untidiness of his person and of his room, which was very foreign to him when he was well, and unconcern for his future. He was then given a series of intravenous injections of arsphenamin and was discharged from the hospital seven weeks after his entrance. During that time he had gained 20 pounds. He went to a sanatorium, where he continued to receive antisyphilitic treatment, with both arsphenamin and mercury, for another six weeks.

Four months after he had come under observation he returned home, and he received no further treatment for three months. At the end of that time the serum Wassermann reaction was weakly positive, but the cerebrospinal fluid remained negative. His physician put him under treatment again and continued treatment for about a year. Altogether he received about thirty intravenous arsphenamin treatments, four intraspinal and scores of inunctions and injections of mercury.

LATER HISTORY

I recently saw him again. More than three years had elapsed since he left the hospital. He related that a few weeks after he returned home, that is, six months after the beginning of the illness that is chronicled above, he obtained employment with a firm that sold automobile accessories and stayed with it two or three months, but as he did not get on very well he left and went with an automobile firm. This firm did not value his services, and after a short time he was again looking for employment. He secured a position with another mercantile firm, and remained with it six or seven months, but not making any progress he changed again and went with the General Electric Company, where he remained two years, during which time he never received an advance of wages. At a time when \$50 a week was considered an acceptable wage for the average worker, he was earning only \$21. To make matters worse, they gave him less acceptable work. This he considered an affront, and he decided to leave them; then he secured a job with another

company, but to little financial advantage. He made no effort to return to the work in which he was trained, namely, the charge of a department in a large store. On being asked why he did not do so he replied that he was convinced he could not do the work satisfactorily, not because he was not well or because he had any difficulty in dealing with people, but, as he expressed it, "I can't think readily of the things to say that would facilitate the work that I would have to do." In other words, he realized that he had become a little indifferent, lacking in the mental elaboration that should be externalized in speech, inclined to be laconic in his answers, and silent. He thought that there were some people in the organization in which he had worked that might be interested in him and that they might give him an opportunity should he solicit it, but he had not been able to bring himself to do it.

He had no particular complaint, and he admitted that he felt well. Nevertheless, he had keen insight of his condition, as illustrated by his remarks about his previous position and by a realization that his wife had abandoned him because he was not able to provide for her. He also realized that his best efforts were not being translated into considerable money. His mother related that he was a little indifferent and that he had few social and no civic interests. His diversions were very simple and childish. Practically the only thing he cared about doing was to go to moving-pictures. He had not kept up with his friends, and he manifested very little inclination for social contact. It was not so much that he did not participate in ordinary pleasure and relaxation as that he had no initiative to plan them or to prompt them. He was not lacking in certain kinds of energy, for when he was out of a position, whether from his own volition or the desires of others, he set resolutely to work to find another; but the work he accepted was not consistent with his education or with his position in life, nor did he attempt to utilize former experience to help him to any position. On examination, the most striking defect was on the affective side of his consciousness. Memory and attention were but slightly impaired. He recalled the incidents of his illness, the room that he occupied in the hospital, where he went after leaving the hospital and how long he remained there, and a great many incidents of his illness; but when he attempted to particularize them, he displayed slight amnesia. On effort he had very commendable capacity for attention. For instance, when the paragraph of a newspaper was read to him, although he did not seem to be paying keen attention, nevertheless he repeated the substance of it without particular hiatus.

But his unfortunate experience had congealed him emotionally. Nothing appealed to him very much save the satisfaction of physical needs. His wife had forsaken him, the career in which he had made a success was closed to him, his mother manifested concern and despair, but they did not seem to touch him. He treated the situation and the prospective sterility of life for him as if they were matters of no importance. To all outward appearance and in casual contact he was quite normal. Spiritually, however, he was but an image formed in the likeness of his previous self.

Physical examination revealed no evidences of organic disorder of the central nervous system. The pupils, tendon jerks, the muscle tonus and the capacity for coordination were quite normal. There was no tremor, no disorder of speech, no disturbance of sense or sensibility. The only physical abnormality was a sluggish vascular system: bradycardia and poor peripheral circulation. Although he did not give the impression of vigor, he had regained his weight; and his appearance was that of a man in good health. His Wassermann reactions had been persistently negative for two years. His soul bore the syphilitic scar, and it will continue to bear it until he yields the spirit. It would be difficult to find a more instructive example of the curability of syphilis of the nervous system in the ordinary sense of the term. But what a miscarriage of therapeutic justice, what a mockery of our studied effort. Though cured, he is but the simulacrum of his former self.

COMMENT

The experience is instructive, in that the encroachment of the central nervous system by the spirochete occurred while the patient was under antisyphilitic treatment by mercury; and more instructive is the experience that the symptoms yielded so promptly to intensive arspenamin and mercury treatment. Although it is impossible to say how long the infection had been in existence when the meningeal symptoms displayed themselves, it is probable that it was more than a year. Had it not been that his wife showed a florid syphilis, there would have been no information concerning his affection.

That the burden of the pathologic process was borne by the meninges of the base of the brain is evidenced by the facial paralysis and by the vertigo; but that there was also inflammation of the cortical meninges is indicated by the stupor, the apathy, the disturbed cerebration and the sequelae.

The information furnished by examination of the cerebrospinal fluid tended to corroborate the diagnosis of predominant meningeal involvement. It is worthy of note that at no time did the patient complain of headache; nor were symptoms that are given much weight as important diagnostic accompaniments of basilar meningitis, such as nuchal rigidity, basilar and cervical tenderness and diplopia, present.

No satisfactory explanation can be given of the Babinski great toe phenomenon elicited in both feet during the first few days of his profound cerebral illness. The only explanation that can be given is that there was a meningeal involvement over the cortical motor areas. One would expect that in such a condition there would be evidences of motor irritation or of motor inhibition; but as these were lacking, it must be assumed that an associate edematous condition of the superficial cortex prevented manifestations of the one or the other. Indeed, the clinical picture which the patient presented at the height of his disease was not at all unlike that of certain cases of wet brain of alcoholism or of influenzal encephalitis, and it may legitimately be assumed that the dislocation of the patient's mental components was caused by a pathologic condition made up of inflammation and edema not unlike that which occurs particularly in the latter disease.

The chief object in calling attention to this variety of cerebral syphilis is to emphasize the fact that although the infection is thwarted and the patient regains what seems to be his health, he is left with a scar of his mind and his emotions which permanently cripples him to a certain degree. It is easy to measure this degree by psychometric test; but the most telling way of expressing it is to say that it has thrown him from the social, civic, marital, financial level that he had attained, which was a commendable one, to a much lower one at which he can barely support himself and can make no contribution to the welfare, the interest or the support of others. Had he been reduced another peg he might have become a hobo, a wanderer or a charge on his family or the community.

Such experiences as these teach us that syphilis of the nervous system is a curable disease; but the lesson that we learn from it is that the earlier the treatment is instituted the greater is the victim's chance of complete functional recovery.

37 West Fifty-Fourth Street.

ARSPHENAMIN REACTIONS

JOHN F. MARTIN, M.D.

Junior Assistant Physician, Department of Dermatology, Boston Dispensary
BOSTON

In large hospital clinics where syphilis is treated with various arspenamin preparations, reactions occur more or less frequently, depending on the care taken in preparing solutions, the purity of contents, the elapsed time between the making of the solution and its administration to the patient, the amount of arspenamin given, operative technic and skill, and factors within the patient. While a given brand of arspenamin might, through some circumstance, very rarely prove toxic, the precautions taken to make such possibilities remote (chemical, animal and clinical controls) usually mean that arspenamin has to be discharged for want of evidence. Arspenamin might have been guilty of causing some of the reactions on which this paper is based, but this could not be proved.

When directions are carefully followed in preparing the arspenamin solution, and in administering it to the patient, if a reaction follows, then the cause of the reaction is attributable either to the brand of arspenamin used or to the patient. Printed directions accompany each ampule of arspenamin, whether it be diarsenol, arsenobenzol, salvarsan or arsaminol, and are specific and easy to understand; and it is laxness in following these directions that accounts for the greater number of reactions to treatment. When a trained and careful person prepares the solutions of arspenamin, reactions will seldom occur in hospital clinics or in private practice.

NECESSARY PRECAUTIONS

One should note any departure from the normal lemon-yellow color of the brand of arspenamin being used, and then immerse the ampule in 95 per cent. alcohol for fifteen minutes to detect obscure cracks. Cracked ampules or ampules that contain discolored arspenamin are to be rejected, the substance having become oxidized. It is a good plan to mark down the serial numbers of the ampules used in order to check up with the manufacturer in case the arspenamin is suspected of being the cause of a reaction. One is further directed to prepare individual solutions, and when this is not practical, not to prepare more solution than can be disposed of within half an hour. Using the syringe-container method, and allowing six minutes for each 0.5 gm. of arspenamin in solution, limits the number of ampules that may be used at one time to five. The sooner the solution is disposed of, the less danger of oxidation.

Using the directed technic for one brand of arspenamin while preparing the solution of another will, in some cases, cause reactions. Salvarsan (Metz) calls for freshly distilled water of not more than room temperature; diarsenol requires warm, freshly distilled water; and arsenobenzol is to be dissolved in boiling hot, freshly distilled water. Salvarsan becomes oxidized when dissolved in hot water. The directions call for freshly distilled water or physiologic sodium chlorid solution, prepared from chemically pure sodium chlorid—not from table salt. It is directed that normal sodium hydroxid (4 per cent.) or 15 per cent. solution be used to neutralize and alkalize arspenamin in solu-

tion. Faulty preparation with impure or altered sodium hydroxid, or contaminated distilled water, may cause reactions.

Neutralizing arspenamin, which is a dihydrochlorid salt, requires a definite amount of sodium hydroxid to render it slightly alkaline and suitable for use. A large percentage of reactions resulting when technic is not strictly followed are due to hypo-alkalization, while hyperalkaline solutions, due to faulty measuring of sodium hydroxid solution, causes reactions at times. A graduated pipet or buret is recommended to be used, the certainty being a normal-sized drop and accurate measure. Arspenamin is precipitated as a basic salt by sodium hydroxid; it requires a definite amount to redissolve the precipitate, changing the basic salt to a monosodium salt, the solution being just alkaline to litmus paper. On further addition of a definite amount of sodium hydroxid, a disodium salt is formed which is completely soluble in water. The basic precipitate and monosodium salt will cause reactions, the disodium salt in solution, properly diluted and filtered, being suitable for use.

All manufacturers agree that solutions should be of room temperature. Injecting too cold solutions into the circulation will induce chill reactions. Too rapid giving of the solution, particularly in high concentration, will cause reactions in some instances. One is advised not to give more than 0.1 gm. of drug (30 c.c. of solution) in two minutes; the gravity method is the one advised; the rate of flow is controlled by the size of the needle (No. 18 or 20 B. & S. gage) and the height of the column of fluid. The syringe-container method is favored by many operators, and while not as "fool proof" as the gravity method, an expert can handle difficult work with greater precision.

Giving too large a dose of arspenamin at the beginning of a course of treatment accounts for some reactions. Lack of preliminary preparation for treatment—a laxative the night before, and a light breakfast four or five hours before operation—is sometimes a cause. Every patient should be given a careful physical examination to determine organic or functional impairments, as findings may limit or contraindicate arspenamin treatment. When two or more reactions occur from a multiple ampule solution, in the majority of instances the fault will be found in the technic of preparing the solution, and the usual cause will probably be hypo-alkalinity.

FACTORS ATTRIBUTABLE TO THE PATIENT

Both arspenamin and the technic in preparing its solution having been excluded, factors attributable to the patient are to be considered. Tissue susceptibility to arspenamin medication include allergic idiosyncrasy, an inherited dominant susceptibility to arspenamin medication; anaphylaxis, protoplasmic sensitization from repeated doses; blood synthesis reactions, in which arspenamin becomes altered or precipitated from causes not understood, or ascribed to excess of carbon dioxid in the blood, or faultily prepared arspenamin solutions; and the nitritoid reaction, ascribed to the action of arspenamin in destroying spirochetes and liberating large quantities of bacterial protein to which the tissues have become sensitized. The Herxheimer reaction is attributed to the stimulating activity of nonsterilizing doses of arspenamin.

Reaction symptoms occur singly or in syndromes, while the injection is being given, soon after the patient

leaves the table, or a few hours or days later. The most common type of table reaction is the vasomotor syndrome, usually manifesting dermal capillary flushing, dyspnea, coughing, nausea and subcutaneous edema, two or more symptoms being present. The vasomotor type of reaction has been ascribed by Pardo¹ and others to the vasodilating action of arspenamin. Insufficient alkalization of arspenamin solutions account for a large number of this type of reaction. Hirano² claims that arspenamin anaphylactoid symptoms are due in many cases to a deficient epinephrin content in the blood resulting from sudden consumption after intravenous injection of arspenamin, and from an inhibition of epinephrin secretion by the suprarenals. When repeated reactions of this type occur, preceded by a number of arspenamin treatments without reaction, epinephrin deficiency as a possible factor causing the reaction is to be considered. Preinjection of epinephrin tends to prevent this reaction, as well as relieve the symptoms when it occurs.

Another type of reaction occurring infrequently, but liable to occur while the patient is on the table, is the "spine pain," characterized by the patient's complaining of stabbing pains in the lumbosacral region. The pain is usually intense; it is in most cases accompanied by vasomotor symptoms, and might be the result of vasomotor influence on various viscera, and registering on respective nerve centers in the spinal cord.

According to Kolmer and Yagle,³ arspenamin causes hemolysis, particularly when injected in concentrated solution, but is not so likely to do so when in weaker solution or when isotonic salt solution is used instead of distilled water. Hemolytic action of arspenamin solutions is said to be increased by hyperalkalization. Dilute solutions of neo-arsphenamin (0.9 gm. in 90 c.c. or more of water) are claimed to cause hemolysis, while concentrated solutions (0.9 gm. in 30 c.c. or less of water) are not hemolytic.

FUNCTIONAL AND ORGANIC IMPAIRMENTS

Reactions other than those due to anaphylaxis and blood synthesis arise from functional and organic impairments causing certain viscera to be more susceptible to arspenamin medication. Neurologic reactions present the hysterical type, usually not attributable to arspenamin but to psychophysical upsets, before or after treatment. Syncope, headache, vertigo, neuritis pseudo-epilepsy, and Herxheimer manifestations affecting special nerve centers occasionally arise, owing either to sensitization, vasomotor action, or activating syphilitic lesions. Reflex emmresis has been observed in two cases, immediately following arspenamin treatment.

Aside from gastro-intestinal manifestations in anaphylactic reactions, there are symptoms that patients complain of at times, such as nausea, diarrhea, colic, anorexia and indigestion. They are not severe enough to be classed as true reactions, but may be termed incidents, being due, in most cases, to functional or organic impairments.

Dermal reactions sometimes occur, and appear to be due to too large doses of arspenamin, dominant

susceptibility, anaphylaxis, faulty elimination, blood synthesis, and the administering of toxic arsphenamin solutions. The eruptions appearing may be scarlatinal, maculopapular, or may simulate dermatoses, as pityriasis rosea.

"Arsphenamin jaundice" is a coined term applied to jaundice manifested by patients who have received arsphenamin medication. There are two forms, corresponding to the catarrhal or hepatogenous, and the toxic or hematogenous, the former being due to obstructive elimination arising from such causes as cholangitis or hepatitis, which may or may not be due to arsphenamin treatment. The hematogenous form is probably due to toxic products of arsphenamin blood synthesis, toxic arsphenamin solutions, sensitized hepatic tissue, or overworked hepatic function, resulting in low-grade or toxic degeneration. Chronic hepatitis may be a contributory cause.

Jaundice following arsphenamin treatment usually occurs after a number of doses of arsphenamin have been given, and it has been observed that patients that show an exhausted or diminished tolerance, manifested by various reactions, are prone to have jaundice at a later period if arsphenamin treatment is carried on without a rest from treatment of one or more weeks. The usual case of arsphenamin jaundice clears up in from two to four weeks; the severe, toxic type of jaundice, while rare, is likely to be fatal.

Reactions to arsphenamin treatment are a warning signal that there is a cause to be found, and that a review of the patient's history, physical condition, the brand of arsphenamin used, and the technic of preparing the solution and administering it to the patient should be undertaken. It sometimes happens that treatment has been too prolonged, in persistently positive cases, and the tolerance to arsphenamin, and also to mercury, has become exhausted. In such cases a rest from treatment of one or two months does much to rejuvenate the patient.

CLASSIFICATION OF UNTOWARD INCIDENTS AND REACTIONS

Sequelae arising from arsphenamin medication may be thus classified: the incidents, slight untoward symptoms occurring in patients with normal tolerance to arsphenamin, such as vertigo, palpitation, disturbances of taste and smell, or slight nausea; the reactions, usually occurring in syndromes, and causing discomfort and sometimes incapacity, which may be ascribed to allergic or acquired susceptibility to arsphenamin, functional or organic complications, or toxic arsphenamin solutions; the grave reactions (sometimes fatalities), such as dermatitis exfoliativa, toxic jaundice, hemorrhagic encephalitis, and gangrene; the accidents, such as thrombosis, phlebitis, and infiltrations about a vein.

With careful observance of all precautions in the administering of a properly prepared arsphenamin solution to a risk-free patient, if treatment is not too energetic, reactions may be reduced to a minimum, both in private practice and hospital clinics. Each patient, during a course of treatment, should be carefully observed as to individual susceptibility and tolerance for arsphenamin. Standard treatment may serve as a guide for the average case, but one must individualize to prevent reactions and best treat the patient.

SUMMARY OF BUREAU OF CHEMISTRY INVESTIGATIONS OF POISONING DUE TO RIPE OLIVES *

G. G. DeBORD, M.S.

R. B. EDMONDSON, A.B.

AND

CHARLES THOM, PH.D.

WASHINGTON, D. C.

In the study of poisoning due to ripe olives, a large amount of material representing this industry and its commercial product has been handled by the Microbiological Laboratory of the Bureau of Chemistry. Every phase of olive handling has been considered. The details of this work will be published elsewhere. A summary of the general findings may be of wider interest than the purely bacteriologic report. In the course of this investigation, 2,161 commercial containers have been examined. Of these containers, 560 were glass and 1,601 were tin. Cultures were made from the first 500 containers opened by us, including both tin and glass. Satisfactory odor and appearance were so uniformly accompanied by sterility that culture was subsequently limited to material which did not pass physical examination. In all, 618 containers were examined bacteriologically, and from these samples many different organisms were isolated, among them *Bacillus botulinus* in the following cases:

ISOLATION OF BACILLUS BOTULINUS

1. *Bacillus botulinus* was isolated from seven glass jars of the same batch that caused the deaths of twelve persons in Ohio and Michigan. The actual olives involved in these two poisoning cases were not seen. Seven jars out of forty-six of the batch examined were shown to contain a highly virulent toxin. The organisms isolated from these jars when tested against antisera proved to be Type A of Burke¹ and Dickson² which type is more commonly found in the Pacific Coast states. Type B, which is more common in the Eastern states and apparently also in Europe, has not been reported thus far in olives, although reported by Dickson as occasionally found in California.

2. The organism was found in bits of dried pimiento stuffing adherent to the inside of an empty glass bottle received from Kalispell, Mont. Stuffed olives from this bottle appear to have caused the death of five persons. Here again Type A was found.

3. *Bacillus botulinus* (Type A) was isolated from the interior of one of the olives from the glass jar connected with the New York poisoning cases.

4. The organism was isolated from the interior of an olive from the original glass bottle concerned in the deaths of seven persons at Memphis, Tenn. It was similarly isolated from two more olives which had been thrown into the yard and later recovered. All of these organisms were Type A. These olives were

2. Dickson, E. C., and Howitt, Beatrice M.: Botulism: Preliminary Report of a Study of the Antitoxin of *Bacillus Botulinus*, J. A. M. A. **74**: 718 (March 13) 1920.

part of a batch closely related to that concerned in the Ohio and Michigan cases.

5. Olive relish which recently caused the death of one person in Richmond, Calif., was examined by Dr. Fellers of this bureau and found to contain toxin capable of producing the death of experimental animals. Preliminary cultural examination indicates the presence of *Bacillus botulinus*. This sample was in tin.

ODOR OF OLIVES

From the standpoint of the safety of the consumer, it is important to know that in all of the material infected with *Bacillus botulinus* examined by us the odor detected when the container was opened, or the odor of the olives when secured separately from the original container, was distinctly offensive. The offensiveness of the olives, if washed, iced or served in connection with highly flavored foods may be reduced to a minimum. It is recorded, however, that some of the consumers in the cases mentioned above detected the spoiled condition and refused to eat them. Others less acquainted with ripe olives or less keen in their sense of smell consumed the product. Some of them later recorded their objection to the fruit before they died. In only one case (New York) was there any expressed liking for the product.

The real difficulty seems to lie in a widespread lack of acquaintance with a normal odor of ripe olives. Many samples showing the whole range of quality from the highest grade to manifestly putrid material were examined and compared. Tabulation of the physical examination at the time of opening checked absolutely with bacteriologic results in the selection of unsound material. It is impossible to select toxin containing samples from other spoiled samples without animal experiments. These results, therefore, emphasize the necessity of careful examination at the time of opening the container, and of the destruction of any suspected material.

STERILIZATION

Bacteriologic examination of the canned samples revealed the presence of many species of organisms other than *Bacillus botulinus*. Among these organisms were members of the colon group and many non-sporulating aerobes. Both our investigations of the time and temperature used in processing and the presence of these nonsporulating organisms in the containers indicate that the amount of heat applied was entirely inadequate for sterilization. Resistant spore-forming organisms when present, as they occasionally proved to be, withstand very much higher temperatures than were used in the majority of plants visited.

The practice of shipping olives and holding them at the factory either in water or weak brine in barrels or tanks appears to be fairly common in the industry. The salt content observed was never high enough to prevent the activity of micro-organisms. The fermentation of the tanks or barrels examined varied from the acid type without gas production to that of putrefactive decomposition with abundant gas. The odor given off from some of the barrels was very offensive. During this holding period, a barrel or tank of olives infected with any particular organism becomes contaminated throughout by its multiplication. The olives from such an original barrel or tank are graded first into several sizes, and then graded again according to color. One such originally infected container, therefore, may contribute infected olives to several of the final lots so packed. Sterilization of food carrying

such extensive contamination with all sorts of organisms is very difficult.

There is another aspect to this fermentation aside from its possibilities of producing a poisonous product. The odor of putrefaction already noted is generally recognized as evidence of a product at least partially decomposed. Decency demands that products so decomposed as to be offensive be eliminated from human food. Such products should be destroyed rather than cleaned up, canned and sterilized.

CONCLUSIONS

1. More efficient sterilization should be employed in order to prevent further outbreaks of botulism.
2. Shipping or holding in brine solutions, if tolerated at all, should be so modified as to exclude any undesirable fermentations.
3. Olives from the time of picking until processed in the final container should be handled with the same degree of care and cleanliness as any other perishable food product.

DENTAL SURGERY AND ORGANIC HEART DISEASE

P. J. CALVY, M.D.

FOND DU LAC, WIS.

In discussing this subject I do not intend to detract in the least from the brilliant results attained by dental surgery in the treatment of disease caused by focal infection about the teeth; rather, I mean to call attention to the very real danger which at times and under special conditions exists when radical treatment by extraction is attempted. Special reference is made to organic disease of the heart.

In a given case in which focal infection does exist about the teeth, together with organic cardiac disease, it is fair to assume, other causes being excluded, that the condition is caused or aggravated by the infection, and treatment for its removal should be instituted; but before this is done, certain results are to be anticipated. Are we going to stir up a latent infection in the heart and create an acute condition which may endanger the patient's life? This is possible. It has come to be accepted as proof of the accuracy of the diagnosis and the necessity of the operation that if the condition for which relief is sought by extraction of teeth is temporarily aggravated after the operation, the cause of the trouble has been determined and the procedure was justified. The deduction is logical. It is common experience to note that an arthritis or neuritis becomes acutely painful after the infection which causes it is, so to speak, stirred up. It is called a reaction, and is seldom thought of in connection with cardiac disease; but when this reaction takes place and affects a vital organ, such as the heart, results may be serious. Here the diagnostician in internal medicine should take a stand and be the judge when it comes to determining methods of procedure; and dental surgery will have to develop a technic which will reduce this danger to a minimum, as it is positively to be reckoned with.

Drainage of the infected area, such as an apical abscess, is the result which is desired; but this result, at times, and under certain conditions, is precisely what is not obtained, unless proper technic and after-treatment are employed.

After extraction, if the tooth socket is examined at any time during the first three or four days, it is found

to be filled with a firm clot of blood, which precludes drainage and affords an ideal soil for the rapid growth of bacteria; and the traumatism to the structures around the tooth greatly increases the opportunity for absorption. It is under such conditions that there is a rapid rise of temperature, increased pulse rate, and an acute attack or exacerbation of a chronic trouble, as exemplified by the history of the subjoined cases.

REPORT OF CASES

CASE 1.—A thin, anemic woman, aged 42, came seeking relief for attacks of vertigo and general weakness, complaining also of having precordial pain and irregular heart action. Examination of the heart revealed a systolic mitral murmur, slight dilatation and an intermittent action, with nothing in the general history to account for the condition. The throat was negative. The teeth showed evidence of trouble. A hard swelling was found on the alveolar process of the jaw in the region of an impacted and partially unerupted third lower left molar. Pus was oozing out of a small opening on the top. The patient said that this condition had been present for five or six years. Roentgenograms of all the teeth revealed abscesses of the third lower left molar and second bicuspid. Extraction was advised, and the teeth were removed at the hospital the following day by a very competent man. Twelve hours later the temperature had risen to 102.5, and the pulse was 110; thirty-six hours later the temperature was 104, and the pulse 130. The tooth sockets were cleaned out and irrigated with an antiseptic solution, and in three hours the temperature had dropped to 100 and the pulse to 110. Twenty-four hours later another rise of temperature and pulse rate took place. Irrigation of the tooth sockets was again resorted to, with the same results. Thereafter irrigation and cleansing by antiseptic solutions prevented a further rise in temperature and increase in pulse rate.

On the fifth day after extraction, the heart trouble had become worse, the pulse rate remained high, the intermittent heart action was more pronounced, the murmur was more audible and the patient was very weak, being obliged to remain in bed for two weeks under treatment directed to the condition of her heart.

CASE 2.—A woman, aged 64, had an exploratory laparotomy performed for suspected recurrent carcinoma in the pelvis, hysterectomy having been performed three years previously for cancer of the uterus. Examination before operation disclosed hypertrophy of the heart, the systolic blood pressure being 140, and the diastolic, 110. A slight systolic murmur was present at the apex. The patient remained in bed in the hospital for a week before the operation. Laparotomy was performed, but it amounted to nothing more than an exploration, and I do not think it could be held responsible for the results, as the patient recovered from the short ether anesthetic and operation in a few days. On the eighth day after the operation she requested to have two lower second bicuspids extracted, saying that they were sore and had been giving her trouble for a long time. Extraction was done under local anesthesia. Twenty-four hours after extraction of the teeth, the temperature rose to 101, and the pulse to 125. Local treatment, as in the previous case, improved the symptoms somewhat. During the next twenty-four hours the pulse became weaker and more irregular, but the temperature did not rise above 100. The mitral murmur became more audible, the systolic blood pressure began to fall, the pulse rate and general weakness increased, and the patient died of dilatation of the heart at the end of the third day.

COMMENT

Other and as typical cases can be reviewed from private practice and from the records of St. Agnes Hospital, where severe cardiac actions have occurred after the extraction of infected teeth.

It is not to be presumed that all patients with cardiac diseases are necessarily poor risks for extraction; but when the focus of infection to be eradicated is the probable cause of the heart trouble, the possibility of

making matters worse must be borne in mind. No doubt valvular disease in well compensated hearts, especially in young persons, cannot be considered dangerous; but in older persons in whom the myocardium is degenerated, accompanied by valvular disease, when the energy index is low and cardiac decompensation is imminent, such hearts show that they are beginning to break under their load, and in such cases it behooves us to make haste slowly.

ACUTE MIDDLE EAR INFECTIONS
IN CHILDREN

FROM THE STANDPOINT OF THE PEDIATRICIAN *

LINNAEUS EDFORD LA FÉTRA, M.D.

Visiting Physician in Charge, Children's Medical Division, Bellevue Hospital; Associate in Diseases of Children, Columbia University College of Physicians and Surgeons

NEW YORK

Among infants and children, acute ear infections take rank in number and importance only second to respiratory and gastro-intestinal disturbances. They are a common occurrence in affections of the upper respiratory tract, and frequently prove formidable complications in scarlet fever and measles. In private practice among children, hardly a day passes during the winter season without one's coming across an acute ear inflammation, and in hospital practice it is not an uncommon thing to have to incise two or three drums daily in the infants' wards during the season of respiratory infections. Being acquainted with this susceptibility to ear infections, the pediatrician is always on the lookout for ear inflammations, and consequently is likely to see their development from an earlier stage than does the otologist. Routine examination will frequently reveal the ear inflammation before the baby has shown any manifestations referable to the ear by the mother or the nurse.

As to symptoms, complaint of pain in the ear, if present, is of course important; but young infants do not well localize their pains, and frequently a baby will cry and put his hand on the abdomen, and complain of pain in the stomach, when examination will reveal a bulging drum as the cause of the pain. Rolling the head or putting the hand to the ear are suggestive, but often they have no significance. Absence of any complaint of pain or even of general restlessness is no proof that the ear is not inflamed. Temperature elevation is nearly always present, but this also, like pain, may be absent even when the drum is bulging. Tenderness in front of the ear is a very reliable sign, but this too is occasionally lacking even when there is high temperature and bulging of the drum. Moreover, many children deny tenderness, in spite of the involuntary wincing of the mouth. Stiffness of the neck is occasionally present even without enlarged lymph nodes under the mastoid muscle and without mastoiditis. To sum up the indications of middle ear disease, a bulging drum is the only diagnostic sign. On examination, retraction of the drum and in addition some redness is frequently the first sign of inflammation in the rhinopharynx and often confirms a suspicion of acute rhinitis as cause for fever up to 102 or 103 F. when there is as yet no running or stuffiness of the nose. The next sign of ear involvement is some red-

* Read before the Section of Otolaryngology, New York Academy of Medicine, Feb. 13, 1920.

ness along the malleus, and the next, some fulness and redness of Shrapnell's membrane. These signs are present so commonly with head colds in children, and subside so readily, that this small degree of otitis can be considered a very common accompaniment of acute rhinitis.

The next signs that appear mean an otitis media, namely, redness and bulging of the drum membrane, first behind and later in front. Occasionally the drum looks only gray, owing to thickened epithelium, which must be removed to get a view of the drum itself. The retraction meanwhile increases, and the appearance of the drum is that of a small red ring or doughnut. When accompanied by a high temperature, these signs are sufficient justification for incision of the drum; but by far the larger number of such cases will subside in a day or so if the nostrils are treated by a weak epinephrin solution, and hot irrigations of the ear are employed. I find that most otologists incise such drums, and the practice is undoubtedly a good one, for such an ear will frequently return to normal more quickly after being incised than if not opened. I have seen this in many cases when both ears became inflamed successively and in which the first one was incised. I appreciate fully the dangers of fulminating mastoid, and am aware that the knowledge and experience of such cases is the reason why the otologist practically always makes an incision when he sees a bulging drum. And yet the making of an open wound with the dangers of additional infection from the outside has seemed to me a procedure to be avoided, if possible without risk to the child. It is only when the temperature is high, the pain acute and the bulging marked that I have deemed it best to incise at once. The infrequency of mastoid complications and the very satisfactory results of conservative treatment are my justification for awaiting further indications than those of the day of onset. If the tenderness elicited by pressure on the tragus increases, if there is tenderness of the tip of the mastoid, and if the temperature remains high after twenty-four hours and the bulging persists, incision is necessary.

The paracentesis should be done under anesthesia, preferably chloroform, though an exception may be made to this rule if the patient is an infant and only one drum is to be incised. The incision should be a J or U shape, and should be carried well upward. Irrigation with hot boric acid solutions immediately after incision is of advantage, and it is always satisfactory to hear the child gulp or swallow during this irrigation, as this shows a free opening through the drum, with passage of the irrigation fluid into the throat. The temperature, the pain, the tenderness in front of the tragus, and the tenderness of the tip of the mastoid—if that has been present—should all subside after two or three days. It is quite common, however, for the temperature to remain elevated until the discharge becomes purulent. This may be two or three days after the incision.

Mastoid involvement has been, in my experience, a very infrequent complication of middle ear disease; among infants in hospital practice not more than 1 per cent. and in private practice not more than 2 per cent. There is, however, great variation in different years. For several years I saw not a single case in private practice, the next year six or eight, and then a number of years only one or two cases. The rarity of mastoid complications in infants' wards of hospitals is worthy

of comment, not more than three or four a year occurring among hundreds of cases of acute otitis.

During the month of January, 1920, there were in the children's wards of Bellevue Hospital 248 admissions; eleven patients had primary otitis media and thirty-one had otitis secondary to other conditions, mostly of the respiratory tract. There were among these respiratory conditions seven cases of bronchopneumonia, six of bronchitis, four of acute pharyngitis and two of lobar pneumonia. During the year 1919 there were only two cases of mastoiditis among 400 cases of otitis media. It is a common observation that in cases of bronchitis or bronchopneumonia the complicating otitis media occurs usually from four to seven days after the onset of the primary disease. Often in cases of bronchitis the ear will become involved after the temperature of the acute bronchitis has subsided to normal. In these cases it is probable that the continued coughing of the early convalescent stage causes an infection of the eustachian tubes.

The otitis that complicates measles is far more likely to result in mastoiditis than we have been taught to believe, and is almost as serious as the otitis complicating scarlet fever.

The chief reliable sign of mastoid inflammation is sagging of the posterior superior quadrant of the drum with the adjacent wall of the canal. Tenderness above the tip on a line directly behind the meatus at the site of the mastoid emissary vein, and tenderness of the upper part of the mastoid in the region of the zygoma are very important if they can be elicited. Other suggestive signs are a profuse discharge or the sudden cessation of a profuse discharge. In little babies, and occasionally in older children, an edema over the mastoid process is important. It should be emphasized that vacillations of temperature without the canal signs are not reliable, though if these temperature elevations are continued and unexplained by pneumonia, pyelitis or by gastro-intestinal disturbance, they must be regarded as pointing to mastoid involvement. If successive blood counts show an increase in the number of polymorphonuclear cells and in the total leukocyte counts, they are also valuable; but single blood counts are of little importance since the blood in children is susceptible to a polymorphonuclear and total leukocyte increase.

To my mind the indications for the mastoid operation are a persistence of the signs already mentioned, in spite of free drainage through the wide incision in the drum. It is manifest that if the inflammation is not subsiding there must be increasing destruction of the mastoid cells, and the only method of cure is by posterior drainage through the mastoid bone, together with clearing out of all the cells and bony tissues that are infected.

Sinus thrombosis is so exceedingly rare in my experience that I can say very little about those signs. In several instances, however, this diagnosis has been suspected chiefly because of a marked septic type of the temperature curve. It cannot be emphasized too often that marked vacillation in the temperature is a most unsafe guide to either mastoid disease or to sinus thrombosis. The temperature in children is so readily changed by slight causes that there must be localized evidence in order to make a diagnosis. Particularly, one should be on the lookout for pneumonia, pyelitis, tonsillitis, inflammation of the lymph nodes in the neck, and gastro-intestinal disturbances. During epidemics of grip it may be impossible to find any local condition

to explain the temperature variations; but without definite evidence of trouble in the mastoid or in the signs as determined by positive blood cultures, such diagnosis should not be made. In a baby, aged 19 months, sinus thrombosis was suspected but did not exist, and in another instance sinus thrombosis was suspected, probably because of tenderness along the mastoid muscle. This tenderness was an inflammatory reaction in the edge of the muscle extending down from the mastoid process, which had been opened.

Of actual labyrinthine disease complicating mastoiditis I have seen only one case; it is, of course, very rare.

I have said nothing with regard to operations of mastoid and sinus, because they belong distinctly to the realm of the otologist. My plea to the general practitioner and to the pediatrician with regard to ear infections in children is that careful routine examination of the ears be made in all cases in which fever is present. It cannot be emphasized too often that to the man who treats children, the otoscope is just as necessary as the stethoscope.

113 East Sixty-First Street.

USE OF MERCUROCHROME-220 AS A GERMICIDE IN OPHTHALMIA NEONATORUM

A PRELIMINARY REPORT

C. A. CLAPP, M.D.

Assistant in Clinical Ophthalmology, Johns Hopkins University

AND

M. G. MARTIN, M.D.

Senior Resident Physician, Baltimore Eye, Ear and Throat Hospital
BALTIMORE

Since the appearance of the article by Young, White and Swartz,¹ calling attention to the germicide dibromoxymercurofluorescein (mercurochrome-220), showing its penetrating power as well as its germicidal action on the gonococcus, with its slight irritability, we have used it in four cases of gonococcal ophthalmia neonatorum with exceedingly satisfactory results:

CASE 1.—M. D., aged 3 weeks, whose eyes had discharged pus since birth, the only treatment having been boric acid irrigations, was brought to the dispensary of the Baltimore Eye, Ear and Throat Charity Hospital for treatment, Jan. 6, 1920. Examination revealed the typical acute gonorrheal conjunctivitis with swollen lids and purulent secretion, the cornea being clear. Smears showed many pus cells containing gram-negative diplococci. A 2 per cent. solution of mercurochrome was freely instilled in each eye at the hospital, and boric acid irrigations were continued at home as before.

January 7, the lids were not glued together, there were no crusts at the margins, the edema was subsiding, and there was only a small amount of pus in each conjunctival sac. Smears were taken and no gonococci were found. The eyes were again flushed with the 2 per cent. solution, and boric acid irrigations were continued.

January 9, edema of the lids had disappeared: no free pus and no gonococci were found in smears. The eyes were again flushed with the 2 per cent. solution.

January 10, there was no purulent secretion, and a smear was negative. The 2 per cent. solution was again instilled. Although instructions were given to return in two days, the patient was not observed again.

CASE 2.—A. T., aged 11 days, appeared for treatment at the Baltimore Eye, Ear and Throat Dispensary, Jan. 6, 1920, being brought by an aunt who said that the child was delivered by a midwife and no drops were used. Its eyes became sore three or four days after delivery. Examination revealed acute purulent ophthalmia neonatorum with edema of the lids and much free pus, the right lid being more swollen than the left. The corneas were clear. A smear showed numerous pus cells with gram-negative intracellular diplococci. A 2 per cent. solution of mercurochrome was used at the hospital after cleansing with boric acid, and a similar solution was given the aunt with instructions as to the method of use every two hours.

January 9, the left conjunctival sac was almost entirely free from pus, and edema of the lids was much less, the right lid being still swollen. A purulent secretion still showed gonococci, but there was much less secretion and the organisms were fewer. The treatment was ordered to be continued.

January 12, the patient was admitted to Sydenham Hospital with a diagnosis of acute indigestion, and died, but no connection was attributed to eye treatment by the physician in charge. The note in reference to the eyes was that "they were almost free from inflammation."

CASE 3.—B. R. was born in Maryland Lying-In Hospital, Jan. 10, 1920, and Crede's method was employed. Nine days later the lids became edematous, with purulent conjunctivitis which showed an abundance of gonococci. A drop of 1 per cent. silver nitrate solution was instilled into each eye with cleansing, and 10 per cent. argyrol was used every three hours.

January 21, all the symptoms were exaggerated, the discharge being very profuse and the lids edematous, although the cornea remained clear. At 5 p. m. on this date a 2 per cent. solution of mercurochrome-220 was used, and was continued every three hours in place of all other treatment.

January 22, the eye showed marked improvement, the edema of the lids and the secretion both being lessened.

January 23, there was no edema of the lids, but there was considerable serous discharge: no gonococci were found in smear.

January 24, there was a slight serous discharge.

January 26, the patient left the hospital. The secretion was very slight and no gonococci were found.

February 4, the mother reported that the child's eyes were normal.

CASE 4.—A. D. had a smear taken from the eyes two days after birth, as the mother had been under treatment, although the baby's eyes showed no inflammation. The smear showed the presence of gonococci. Two per cent. solution of mercurochrome was instilled every two hours. Three days later no gonococci could be found on staining a smear.

COMMENT

It is not necessary in a report of this character to go into the chemistry or the experimental data of this new germicide, as they were thoroughly treated in the article referred to; nor do we present this as a new sure cure. Rather do we wish to call our colleagues' attention to its application in eye infections, especially infections with the gonococcus. While we have used it in some other infections, it has not seemed as yet more efficacious than the older remedies.

To be sure, these infants frequently improve on cleansing treatment alone, but there seemed a very marked improvement on using the new remedy. The crucial test will come in the cases of gonorrheal conjunctivitis in the adult. While we did use it in the last stages of one case with seemingly marked improvement, we do not feel justified in including it in this report.

A 2 per cent. solution can be used with impunity and with only a slight burning effect for the first few seconds. Though it is rather disagreeable to use on account of the red stain, it is no more objectionable

1. Young, H. H.; White, E. C., and Swartz, E. O.: A New Germicide for Use in the Genito-Urinary Tract: "Mercurochrome-220," J. A. M. A. 73: 1483 (Nov. 15) 1919.

than argyrol, and will not produce a permanent stain, as occasionally happens with the silver preparations. In the cases reported there was a marked improvement after its use was begun, and apparently a much more rapid convalescence.

THE METABOLISM OF A DWARF

STUDIES IN METABOLISM: I

FRITZ B. TALBOT, M.D.

BOSTON

The metabolism in this case is recorded because in the first place it is somewhat unusual, and in the second place no other studies on the metabolism of dwarfs of the same age have been made.

REPORT OF CASE

F. D., a boy, had been under the observation of the overseers of the poor, and had always been placed in excellent homes. The family history was unknown. He was very small and thin in spite of the fact that he had had plenty of good food and outdoor exercise. He had had none of the infectious diseases. At 3 years of age he was much undersized, and is said not to have gained much in weight or size since that time. When 7 years old he weighed, when dressed, 12.6 kg. (27 pounds, 5 ounces) and was 91.5 cm. (36 inches) tall, the normal weight for the age being 21.9 kg. (48 pounds, 1½ ounces) and the height 114.3 cm. (45 inches). His physical examination, aside from his small stature, was normal. A diagnosis of a dwarf boy with rickets was made. His basal metabolism is given in Table 1. The figures represent the basal metabolism without food. His temperature was 98.8, and he had had nothing to eat since midday.

Table 2 shows the results of his metabolism studied during two active periods while fasting and with a temperature of 99.7 F. He weighed at this time 12.93 kg.

The recent work of Benedict and Talbot,¹ about to appear in a forthcoming publication of the Carnegie Institution of Washington, gives, for the first time, the

TABLE 1.—BASAL METABOLISM, MAY 17, 1918

Carbon Dioxide Produced Calculated to Hour Basis, Gm.	Heat Produced per 24 Hours				Average Pulse Rate	Relative Activity
	Total Calories	Per Kilo-gram, Calories	Per Square Meter			
			Lissauer, Calories	Du Bois, Calories		
11.22	777	58	1,335	1,257	104	I asleep
11.32	784	58	1,347	1,269	105	I asleep

complete curve of the basal metabolism of children from birth to puberty, and makes possible comparisons which in the past were not feasible.

The basal figures found for F. D., as compared with the normal studied by us, showed that his total metabolism for twenty-four hours was 780 calories against an average of 900 calories for normal boys of the same age. Although his metabolism was slightly diminished, it was almost within the variation of the normal. When the total calories of F. D. were compared with the total calories of normal boys of the same weight, it was found that he was producing more calories than the average, the total calories for F. D. being 780 against 675 calories for normal boys. This is slightly above the possible variation from the normal.

His metabolism, studied from the point of view of unit of body weight, was found to deviate markedly from the normal. His calories, 58 per kilogram, against the average for normal boys of the same age, 40 calories per kilogram, show an increase of 45 per cent., and his metabolism per kilogram of body weight an increase of 13.7 per cent. above the normal. It is evident, then, that the intensity of his metabolism is greater for each unit of body weight than that of a normal boy. His variation from the normal is striking, and although possibly characteristic of certain types of dwarfs, it may be due to the fact that there is very little fat on his body. As might be expected, his metabolism per unit of body surface was 12 per cent. higher than that of normal boys of the same age, and 11 per cent. higher than that of normal boys of the same weight. This is probably because of the relatively large amount of active protoplasmic tissue and the absence of the inert blanket of body fat, as well as the relatively increased amount of body surface.

TABLE 2.—METABOLISM WHILE FASTING, MARCH 25, 1918

COMMENT

There is no evidence in the physical examination or clinical status of this boy to explain his failure to grow or to prove that he suffered from any disturbance of the glands of internal secretion. Intellectually he was said to be up to other boys of the same age. He had no disturbance of digestion, and his dwarfism may have been merely another evidence of infantilism. His metabolism showed that he did not belong to the class of individuals who have diminished glandular secretion, as in cretinism, myxedema, or hypopituitarism, in which there is a lowered metabolism.

The maximum number of calories used by him shows that when he was restless, even while lying flat in the respiratory chamber, his metabolism would increase nearly 50 per cent. It is evident, of course, that with more active exercise, his metabolism would have increased very much more. It is fair to assume, therefore, that his protoplasmic mass must work at a greater rate of speed than is the case in children who have deficient glandular secretion. It is possible that his increased metabolism might be due to excessive activity of some gland of internal secretion for which no clinical sign was found.

The result of the metabolism studies on this boy show that in order to make him gain in weight he must receive as many calories as a normal boy of the same age, and a great many more calories per kilogram than a normal boy of the same age or weight. Undoubtedly he will require at least twice as many calories as the basal metabolism gives, or approximately 120 calories per kilogram. This is similar to what was found to be true in atrophic infants who required from 160 to 180 calories per kilogram before they gained.

311 Beacon Street.

1. A preliminary communication on this work (Benedict, F. G.: Energy Requirements of Children from Birth to Puberty) appeared in the Boston Medical and Surgical Journal 181: 107 (July 31) 1919.

Differential Diagnosis.—In appendicitis beginning suddenly there is a rise in temperature; in acute perforation of the stomach or duodenum the temperature falls.

THE SUBOXIDATION SYNDROME IN
CHILDHOOD

CHARLES GILMORE KERLEY, M.D.

AND

LOUIS BERMAN, M.D.

NEW YORK

The condition which we have designated as the "suboxidation syndrome" is found with few exceptions among the offspring of the well-to-do. The forebears of the children presenting this syndrome are usually those who have lived indoor occupational lives for two or more generations—those who have been occupied with intellectual pursuits and not by manual labor.

A child with the suboxidation syndrome is one whose physical functions are habitually below the normal. He may be overweight, or of average weight, but he is usually underweight. There is a lowered capacity in endurance, and the emotional control is defective. As a rule, the child is precocious and mentally overactive, and possesses much nervous energy. One of the striking features is a dryness of the skin with a tendency to erythema and mild eczema. Patchy areas of inflammation are particularly prone to appear about the mouth. Perspiration is scanty, and the child rarely perspires except on very hot days, and then only under active exercise. The hands and feet readily become cold in cold weather, and this feature is complained of by the parents. They feel low temperature keenly. Extra heavy outdoor garments are required during the winter months. A moderate anemia is present in most cases. The appetite is often capricious, and constipation is the rule.

One of the frequently encountered features of this syndrome is a marked tendency to febrile rhinitis and bronchitis. The child is scarcely free from one attack when another supervenes. There is a chain of these respiratory affections throughout the winter. The "colds" are sufficiently severe and frequent in occurrence to interfere seriously with the activity of the patient, and much time is lost in school and outdoors. It is rare to find a patient of this type who has not had both tonsils and adenoids removed, with little or no benefit.

As a class they are rather immune to infection of the respiratory tract, although pneumonia and infectious bronchitis may, of course, occur. While they show a certain resistance to bacillary affections of the respiratory mucous membrane, they quite frequently are subjects of protein sensitization; and bronchitis, when it occurs, is likely to be of the spasmodic type.

Another feature of the syndrome is the tendency to attacks of recurrent vomiting. The child vomits once or repeatedly for a few hours or a day or two. The vomiting seizures may have occurred at fairly definite intervals for several months or years.

In some of these patients, transient skin rashes or eczema may be the predominating manifestation that brings him to us; or it may be because of the anemia or that he is underweight or that he has not gained in height for a period of several months.

Others will give the history of an elevation of the temperature, lasting one or more days, occurring at fairly regular intervals, without other manifestations than those of heavy breath and a coated tongue.

Not all cases show an identical train of acute manifestations. In one respect, however, these children are

very similar: They have a defective metabolism for the soluble carbohydrates and for the hydrocarbons, particularly for cow's milk fat in the amount that we have accustomed ourselves during the last few decades to give to children.

ILLUSTRATIVE CASES

CASE 1.—A boy, aged 3 years, weighing 29 pounds and without physical abnormality, had been subject to recurrent attacks of elevation of the temperature since the age of 1 year. They occurred about every two months. There was loss of appetite, coated tongue and listlessness, with a temperature of from 101 to 103. There was rarely vomiting, the fever periods lasting from three to five days. The skin showed scattered areas of erythema. He was put on a diet free from cow's milk fat, and sugar. During the next eight months there were no further attacks of illness, and he had gained 3½ pounds in weight and 2½ inches in height.

CASE 2.—A girl, aged 6 years, who weighed 47½ pounds and who was without physical abnormality, had a habitually coated tongue and habitually poor appetite. Meal times were a trial to the other members of the family. In disposition she was irritable, her complexion was sallow, the skin was dry over the back of the neck, where there was persistent erythema. There were patchy areas of eczema about the mouth, causing considerable disfigurement. She was subject to frequent catarrhal colds. One followed the other so rapidly that it was difficult to say when one was finished and another began. Tonsils and adenoids had been removed without benefit. It was with concern that the parents looked forward to the approaching winter. She was given a diet from which sugar was largely excluded, enough being allowed to make the food palatable. Butter was forbidden. One pint of skimmed milk was allowed daily. Aside from these restrictions, the food given was that of any well child of her age. After two months under this management she weighed 53 pounds, a gain of 6¾ pounds. There had not been a day's illness. The tongue was clean, with no trace of eczema. She was happy and good natured. During the last six months there have been only two slight colds, and the skin remains clear.

CASE 3.—A girl, aged 8 years, weighing 51½ pounds, gave the history of early eczema and difficult feeding, and "had always been on a diet for her skin." The immediate occasion for the consultation was the occurrence of vomiting attacks at intervals of from four to five weeks. The attacks usually lasted from one to two days, during which time the vomiting occurred frequently. The tongue was much coated at this time, and there was a moderate elevation of the temperature—from 100 to 102. After a seizure she was left very weak, and required several days for recuperation. The heart and lungs were normal. The blood showed 50 per cent. hemoglobin, the red cells, 4,700,000. The urine was entirely negative. She had been taking 1 quart of milk daily in addition to that used on cereals and in puddings. Sugar had been allowed with the customary freedom. She was put on the usual mixed feeding suitable for a child of her age, with restriction to skimmed milk and no sugar. After ten weeks and four days she weighed 56 pounds, a gain of 4½ pounds. The mother reported that during the interval there had been no vomiting and no fever; the tongue remained clean and the bowels regular. This case has been followed for five months without a return of the vomiting seizures.

CASE 4.—A boy, aged 7 years, with a height of 47½ inches and a weight of 42 pounds, came to us, Jan. 2, 1920, because of "frequent colds, persistent wheezing in his chest and a cough which was relieved only by warm weather." The condition had existed for three years, with a particularly severe cough since the preceding November. The patient was thin, pale and weak. The appetite was poor. Food had to be forced. The blood showed 70 per cent. hemoglobin and 4,200,000 red cells. The urine was negative. The heart action was rapid and the heart sounds were normal. Examination of the lungs revealed mucous and sibilant râles fairly evenly distributed. There was slight bronchial spasm. The tonsils and adenoids had been removed. There was no eleva-

tion of the temperature. Acting under medical orders the child had been generally supplied with sugar, cream, milk and butter with the idea of improving his physical condition. Our treatment was to order a general mixed diet largely sugar-free, 1 pint of milk daily, and very little butter. The further instructions were that the boy should remain in bed until 10 a. m. each day, rest one and one-half hours after the midday meal, and retire at 7 p. m.

One pint of a vichy water was to be drunk daily. He was allowed to go outdoors, and no cough mixtures were given. There was a betterment of the cough in three days, with a gradual cessation and entire disappearance in eighteen days. Fourteen days after our first examination the bronchitis had entirely disappeared. After six weeks under treatment, the weight was 47 pounds, a gain of 5 pounds, with a marked improvement in the general appearance of the patient, and an entire absence of cough. The appetite was most satisfactory, and foods such as vegetables and cereals, which the patient previously had to be coaxed and forced to eat, were taken eagerly. The child had remained free from the cough for ten weeks.

COMMENT

A noteworthy feature in nearly every case treated has been the improvement in appetite and the marked gain in weight as soon as the fat and sugars which had been given above the capacity of the patient had been removed from the diet. Foods such as vegetables and cereals which had been taken with reluctance and then in small quantities are often taken eagerly.

The management of children presenting the sub-oxidation syndrome suggested in the foregoing brief case histories will appear in detail in a later publication.

An examination of the urine in a certain percentage of these cases shows a slight but constant acetonuria on an ordinary diet, even when the patients are apparently well. Those subject to attacks of vomiting show a marked acetonuria during the attack. A great majority exhibit a marked acetonuria with acute febrile illness.

A study of the blood by one of us (L. B.) of the patients we have come to classify as "suboxidation syndrome," when apparently well, has shown a variable hyperglycemia varying from 130 mg. of glucose per hundred c.c. of blood as the lowest, to 280 mg. per hundred c.c. as the highest, in a series of sixty-seven cases, the average being 163. Of these, twenty-seven presented themselves with recurrent vomiting, sometimes alternating with bronchitis or eczema as the predominating symptom, and showed an average blood sugar of 175 mg. per hundred c.c.; three who came for recurrent pruritus averaged 170 mg. per hundred c.c.; eleven who exhibited eczema as the predominating symptom averaged 148 mg. per hundred c.c.; two who came for recurrent attacks of fever, with coated tongue and acetone breath, averaged 162 mg. per hundred c.c.; twenty-three who had frequent colds and bronchitis as their chief complaint averaged 160 mg. per hundred c.c.

The blood sugar of ninety-two children not belonging to this group was also examined. These varied between 80 and 125, averaging 105. They included those who came for examination and feeding, for malnutrition, adenoids, intertrigo, enuresis, simple anemia, constipation, proteinogenous asthma, obesity, chronic nephritis, essential headache, chronic cervical adenitis, anorexia, acute bronchitis, tics, nonepileptic convulsions, recurrent vomiting with dilated stomach and redundant sigmoid, recurrent vomiting, frequent colds, asthma due to enlarged tonsils and adenoids relieved by operation, migraine, urticaria, mucous colitis, flat-

foot, chorea, seborrheic eczema of the scalp, cardiac disease, tetany, pylorospasm, gonococcus vaginitis, epilepsy, habit spasm, chronic otitis media and enlarged tonsils.

We have examined four cases belonging to the sub-oxidation syndrome group characterized by attacks of vomiting at the height of the attack. They showed a hypoglycemia, the figures being 80, 85, 85 and 70 mg. per hundred c.c. One case of bronchitis with bronchospasm examined in the attack had 75 mg. sugar per hundred c.c. of blood.

Ten cases classifiable clinically as belonging to the suboxidation syndrome group have not shown any definite hyperglycemia at the time of examination. Of these there were four cases of frequent colds, with an average blood sugar of 105 mg. per hundred c.c.; two cases of eczema averaged 97; three cases characterized by recurrent vomiting averaged 106, and one of recurrent diarrhea showed 105. We believe that a study of their sugar tolerance would show it impaired, and we hope to make a study of their blood sugar curve after the ingestion of sugar.

DETERMINATION OF BLOOD SUGAR

The method used to determine the blood sugar was an adaptation of Benedict's ¹ modified picric and picrate method to finger blood along the lines followed by Epstein in applying the original picric acid method:

Of the blood, 0.2 c.c. was obtained from a finger and was immediately mixed with 0.8 c.c. of distilled water, the blood laking after a little shaking. To this, 1.5 c.c. of Benedict's picric acid picrate reagent was added drop by drop and thoroughly mixed. The precipitated proteins were then thrown down by centrifuging. Of the supernatant fluid, 1 c.c. was taken, 0.5 c.c. of 20 per cent. anhydrous sodium carbonate added, and the mixture, corked with absorbent cotton, was placed in a water bath for ten minutes. This was compared in the Kuttner colorimeter with a standard solution of potassium dichromate, made up by matching against a solution of glucose containing 0.2 mg. to the cubic centimeter, treated as the blood was treated, described above.

MERCURIC CHLORID POISONING FROM VAGINAL INJECTIONS—TWO FATAL

P. BROOKE BLAND, M.D.

PHILADELPHIA

In the local treatment of acute and chronic pelvic affections, vaginal irrigations are valuable and helpful measures. Usually they are harmless; when carelessly and indifferently employed, however, they may result in extensive local organic destruction and occasionally cause death, as emphasized in two of the clinical instances herewith presented.

CASE 1.—History.—Mrs. E. F., aged 29, seen in consultation June 4, 1918, with Dr. George Cunningham, Vineland, N. J., first menstruated at the age of 20, and menstruation had always been regular. It recurred every twenty-eight days, and was not accompanied by pain. The discharge continued from four to five days, and it had always been rather profuse. Frequently it contained clots. She was married at 21, and had had three pregnancies. All continued to full term and terminated normally. She was never sutured.

Present Illness.—Four weeks prior to admission to the Vineland Hospital, the patient took a copious douche of hot

1. Benedict, S. R.: A Modification of the Lewis-Benedict Method for the Determination of Sugar in Blood, *J. Biol. Chem.* 34: 201 (April) 1918.

water, to which were added two "blue tablets," (mercuric chlorid). These were employed, she said, to prevent conception. Very soon after the irrigation, the patient was seized with violent burning pain in the vulva and vagina. The family physician prescribed various agents without relief. The following day, the vulva became intensely swollen and red, and presented all the signs of violent inflammation.

TABLE 1.—BLOOD ANALYSES

	Mg. per 100 C.c. Whole Blood
Jan. 14, 1920:	
Nonprotein nitrogen.....	204
Urea nitrogen.....	97.3
Creatinin.....	10.6
January 19:	
Nonprotein nitrogen.....	330.4
Urea nitrogen.....	102.6
Creatinin.....	11.1
January 23:	
Nonprotein nitrogen.....	370.3
Urea nitrogen.....	152.5
Creatinin.....	11.6

Urination was difficult and extremely painful. This process continued for several days and latterly had been accompanied by a profuse seropurulent discharge. The material frequently contained long pieces of shreds and membrane.

Examination and Course.—Four weeks subsequent to taking the douche the vulva was still somewhat swollen and inflamed. The vagina showed most striking changes. The canal was almost completely closed, and its diameter would not permit the introduction of my index finger. The mucosa had entirely sloughed away and the tube was lined by red, resistant, tender, granular membrane. There were no marked constitutional symptoms at any time. Operative measures were recommended for the vaginal stenosis, but were refused, and the patient passed from the hands of her family physician. No further record could, therefore, be obtained of the case.

CASE 2.—History.—Mrs. E. J., aged 21, admitted to Jefferson Hospital, Oct. 11, 1919, first menstruated at the age of 17, one year subsequent to her marriage. It had always been regular, and of the twenty-eight day type. The flow had been scanty and extremely painful. The last menstrual period occurred Aug. 30, 1919, or approximately two months before her admission to the hospital.

Present Illness.—Two days before, in order to prevent conception, the patient took a douche of hot water to which she added a teaspoonful of "white powder" (mercuric chlorid). One quart of water was used. Immediately after the irrigation she was seized with violent burning pain. The family physician was called, who applied oils and gave the patient an alkaline douche. The treatment gave temporary relief. The following day the vulva became greatly swollen and discolored. The pain was intense. Shortly afterward a profuse seropurulent discharge appeared which later on contained particles of tissue.

TABLE 2.—DIFFERENCE BETWEEN PATIENT'S BLOOD AND THE NORMAL

	Normal, Mg.	Patient's Blood, Mg.	Difference, Mg.
Nonprotein nitrogen.....	From 25 to 35	370.3	335.3
Urea nitrogen.....	From 12 to 23	152.5	129.5
Creatinin.....	From 1 to 2	11.6	9.6

Examination and Course.—The woman was rather delicate. She was suffering great agony. The pupils were normal. The lips were parched, dry and cracked. The tongue and pharynx were extremely red and dry. The mucous membrane throughout the throat was intensely injected. The lungs were normal. The heart presented a moderately loud systolic murmur, and its rate was rapid. The abdomen was somewhat distended, and was rather resistant and tender, especially above the pubic arch. The vulva was found to be extremely swollen, red, tender and in a state of violent inflammation. The labia were pendulous and edematous.

The vaginal orifice was covered with a yellowish green exudate, and a profuse seropurulent discharge, foul and offensive, was pouring from the vaginal opening. Digital examination was attempted, but was impossible on account of the intense pain. The temperature was normal. The pulse rate ranged from 100 to 130. Respirations were practically undisturbed. The urine contained a large quantity of albumin, a great variety of casts, and a large number of white and red blood cells. The general systemic symptoms became worse, and she died of complete suppression of urine, October 18, seven days after her admission to the hospital.

CASE 3.—History.—Mrs. T. S., aged 28, admitted to Jefferson Hospital, Jan. 9, 1920, had always been in good health and never suffered any serious disease. Menstruation began when she was 13. It was always regular and lasted from three to four days. The flow was accompanied by pain on the first day, but there were no clots. The last period occurred Oct. 13, 1919, approximately three months before, her admission to the hospital. She married at the age of 22 and had had three pregnancies. The first pregnancy terminated in abortion at the end of five weeks. This was not induced. The second pregnancy continued to full term, and she was delivered normally. Her third conception occurred, Oct. 13, 1919, and terminated, by self induction, Jan. 8, 1920.

TABLE 3.—URINALYSIS

Date	Specific Gravity	Reaction	Albumin	Sugar
1/14/20	Q.N.S.*	Acid	Trace	Negative

.....	Negative	Many
.....	Negative

* Quantity not sufficient.

Present Illness.—This began, January 8, following a uterine irrigation of hot water to which she added two "tablets" (mercuric chlorid). The douche nozzle was carried deliberately into the cervical canal, and the irrigating material was allowed to flush the interior of the uterine cavity. Immediately thereafter the patient was seized with sharp abdominal pain. This was intermittent in character and occurred about every five minutes. Abortion occurred the following day. A fetus 3 inches in length was expelled, and the placenta and membranes came away one hour later. Subsequently the patient developed vomiting and diarrhea. She also felt creepy and suffered a rather violent chill. She had a profuse bloody discharge, which was exceedingly foul. She also developed general joint pains. Urinary excretion became extremely slight. The skin of the patient became extremely dry, and her mouth cracked and parched. The family physician treated her for suppression of urine and uremia by placing her in hot packs. He was not informed by the patient or husband of the true condition of affairs.

Examination and Course.—The patient was admitted to the hospital with complete urinary suppression. No urine had been passed during the preceding twenty-four hours, and none was passed for four days subsequently. Diarrhea and vomiting were more or less constant. These were uncontrollable. She complained of intense restlessness and violent headaches. She also suffered with a burning sensation in the region of the vagina and bladder. Her mouth was swollen.

The teeth were tender, and the breath was extremely offensive. The eyes were normal. The lips were dry and cracked. The tongue was dry, coated and furred. The throat was injected. The breath was extremely foul. The lungs were normal. The heart action was regular, and no adventitious sounds were heard. The abdomen was somewhat distended and rather rigid and tender over the kidneys and in the midline, low down. The mucous membrane of the vagina was normal. There was a seropurulent discharge from the uterus. The cervix was patulous and allowed the introduction of the finger. A large slough of endometrium was removed during the examination.

The last specimen of blood was drawn on the morning the patient died, and the comparison (Table 2) will show the difference compared with the normal.

A complete blood count, January 10, revealed: hemoglobin, 60 per cent.; red blood cells, 3,130,000; color index, 0.91; white blood cells, 15,800; the red cells appeared to be normal; polymorphonuclear neutrophils, 98 per cent.; polymorphonuclear eosinophils, 2 per cent.; polymorphonuclear basophils, 0; small mononuclears, 9 per cent.; transitionals, 0. January 18: polymorphonuclear neutrophils, 94 per cent.; polymorphonuclear eosinophils, 2 per cent.; polymorphonuclear basophils, 0; small mononuclears, 2 per cent.; large mononuclears, 1 per cent.; transitionals, 1 per cent.

The symptoms of the patient gradually became worse, and she died, January 23, two weeks after admission.

Clinical Notes, Suggestions, and New Instruments

A CARDIAC DEVELOPMENT DEFECT, WITH RETURN TO NORMAL

STAFFORD McLEAN, M.D., NEW YORK

This case will be of interest to those who are consulted regarding prognosis in infants with congenital cardiac conditions.

REPORT OF CASE

History.—The child, a girl, was delivered at the Sloane Maternity Hospital through a vaginal cesarean operation by the late E. B. Cragin. The mother, aged 31, was an eclamptic primipara. She was six and a half months pregnant; her blood pressure was 200 and there was 80 per cent. albumin in the urine. The birth weight was 2 pounds, 1 ounce. On account of the infant's condition the customary measurements were omitted. On the hospital record there is noted a heart murmur present at birth, but there is no mention of cyanosis. A nevus about 1.5 cm. in diameter was present at the outer canthus of the right eye. During the first three months of life this was treated by three applications of liquid air with a good result.

The infant was placed in an incubator, where it was kept for six weeks. The weight on the fourteenth day was 1 pound, 14 ounces. It was discharged from the hospital at the age of 3 months with a weight of 5 pounds, 11 ounces. At 6 months the weight was 5 pounds, 12 ounces. Breast milk was given for the first two months, when modified whole cow's milk was substituted.

First Examination.—The infant was first seen by me when 9½ months old. Its weight at that time was 9 pounds, 13 ounces. It was badly nourished, and was intensely cyanotic over the entire body, the cyanosis being marked on the face, lips and hands. The fingers showed marked clubbing; no cardiac enlargement could be made out. A loud systolic murmur was heard over the entire chest, most intense over the area of cardiac dulness. No difference in intensity could be detected between base and apex. The murmur was not transmitted to the vessels of the neck. The heart rate was 260. The systolic blood pressure was 75. The red blood

cells were 7,000,000, and the hemoglobin was 105 per cent. Craniotabes was present.

Treatment and Course.—The amount of food was increased. cereals were given with a spoon, and before the twelfth month orange juice, beef juice and yolk of hard boiled egg were added. The increase of weight was slow but continuous, and at the twentieth month the weight was 21 pounds, 8 ounces. At this age she was on a varied diet of milk, potato, scraped beef, apple sauce, etc. The murmur did not change in character between the tenth and twentieth month, but the cyanosis became less intense.

The child began to walk at the twentieth month. Examination at the twenty-second month after an interval of two months failed to reveal a murmur, the cyanosis had disappeared, and the clubbing of the fingers was hardly noticeable. When seen again at thirty months there was no clubbing. At 22 months of age she had pertussis. At 25 months of age she had epistaxis several times; this occurred at infrequent intervals until the thirtieth month.

At 32 months of age the child presented a robust, healthy appearance. The physical examination disclosed nothing abnormal. Weight was 31¼ pounds, height 34¼ inches, abdomen 20¼ inches, chest 21 inches, and head 18¼ inches. No enlargement of the heart could be demonstrated by percussion; the apex was in the fifth space, 2½ inches to the

Electrocardiogram by Leads I, II and III; between the corresponding line of successive pairs of ordinates the time interval is one-fifth second. The space between abscissas represents 0.1 millivolt.

left of the midsternal line, the right border was apparently at the border of the sternum.

Roentgenologic Findings.—When the child was 33 months of age, roentgenograms were made by Dr. Archibald H. Busby. He reported: "Plates show no material enlargement of the heart. The right border is about 1 inch to the right of the midsternal line. The shadow at the base of the heart on the left side is rather broad, the cause of which does not appear to be auricular, but rather within the vessels about the heart."

Electrocardiographic Findings.—An electrocardiogram made about the thirty-second month by Dr. H. E. B. Pardee is reproduced here. His opinion was that the record showed an unusual ventricular complex for a child of that age in that it suggested an approach to left ventricular predominance, though this was not frankly developed. He inferred that the heart might have been subjected to some abnormal influence. In his experience the usual electrocardiogram of the R waves or a suggestion of right ventricular predominance. He knew of no congenital anomaly which would lead to a left-sided hypertrophy except aortic narrowing.

Present Condition.—The child is now 5 years, 11 months of age. She is a sturdy, well nourished child with no symptoms or physical signs of cardiac abnormality. The weight is 40 pounds, height 42 inches, chest 20½ inches, and abdomen

20 inches in circumference. She has had none of the infectious diseases of childhood, with the exception of pertussis as noted above. Her heart apex impulse is in the fifth space, $2\frac{3}{4}$ inches from the midsternal line; the second aortic sound is loud but cannot be considered abnormal.

COMMENT

The case is unusual from several angles. It is unusual for pregnancy terminated at $6\frac{1}{2}$ months to result in a living child. It is uncommon for an infant to survive whose weight drops to a point as low as 1 pound, 14 ounces.

Speculation is futile regarding the defect or defects in many of the infants with cardiac symptoms. That the symptoms were due to a developmental defect rather than a fetal endocarditis is borne out by the history and the outcome. It would seem possible that the disappearance of the symptoms was due to the return of the heart to normal rather than to the development of an unusual degree of compensation. A defect in the ventricular septum existing without any associated lesion could explain the symptoms and their subsequent disappearance.

17 East Seventy-First Street.

A NEW INSTRUMENT FOR LIGATING BLEEDING BLOOD VESSELS AFTER THE REMOVAL OF TONSILS

JOHN A. CAVANAUGH, M.D., CHICAGO

The instrument here described has been a great comfort to the originator, as he can leave all patients after tonsillectomy with a feeling of safety, knowing he will not be called because of hemorrhage. The instrument can be used with ease when the bleeding vessel is deep in a cavity, as it requires but little space.

It is similar in shape to artery forceps. On the end of one arm there is a needle about half an inch long; at the end of the other arm is a rounded end, perforated, through which the needle will pass.

Parallel with the arm and extending beyond the perforating area in this arm is a forklike process with two prongs to form a groove between the rounded part and the fork part for the passage of a thread, which is grasped by the needle as it passes through. On the handle of the perforated blade is a spring for the purpose of placing the threads and of holding them taut, which is very essential.

The instrument is now ready for use. The size of the catgut should be noted, for if it is too large it will

Instrument for ligating bleeding blood vessels after removal of tonsils.

not engage in the needle; No. 0 or No. 1 may be used. The catgut should be moistened shortly before use; otherwise it will be stiff, will not remain taut, and will be harder to draw through the instrument and tissue. Every bleeding vessel that shows itself should be tied, as this is easily done and one need not be afraid of future hemorrhage. The bleeding area is grasped with artery forceps. One should take the instrument that is threaded, and introduce it as one would a second forceps, to grasp the tissue deeper, make slight traction on the hemostat and allow the needle to pass through the tissue, which, when withdrawn, leaves the thread buried under the bleeding vessel and engaged in the perforated end of the needle.

As soon as the needle is drawn through with thread attached, the thread in the spring is loosened and the thread will be more easily drawn through. The artery forceps may now be removed, or one may wait until the ligature has been tied.

7 West Madison Street.

A SIMPLE CLAMP FOR MAKING BALKAN FRAMES OF IRON PIPE

GEORGE T. JOHNSON, M.D., TERRE HAUTE, IND.

These clamps can be quickly made by any blacksmith, from materials in general use. Each clamp consists of an iron plate made of one-eighth inch sheet iron, and two U bolts. Four holes are drilled in the plate to admit the free ends of the U bolts. The dimensions given are suitable for use with one-half inch pipe.

Clamp for making Balkan frames of iron pipe.

A joint made with these clamps will not slip under a great load. They will likewise fasten the upright pipes firmly to the ordinary iron bed. If it is desired to make the frame independent of the bed, crutch rubbers serve admirably on the lower ends of the upright pipes and prevent any possible damage to the floor.

It is best to have sixteen clamps for each frame so that one can make any arrangement suitable for the individual case. The accompanying illustration shows how the clamp is applied.

RAPID ABSORPTION OF MERCURIC CHLORID IN A CASE OF POISONING

SEYMOUR DePORTE, M.D., ARDMORE, OKLA.

B., a white girl, aged 21, waitress, was suddenly seized with terrific abdominal pain, and symptoms of a severe gastroenteritis with vomiting and purging. The temperature was subnormal, ranging between 95.4 and 96 F.; the skin was cold and clammy; the pupils were markedly dilated, and the radial pulse was not perceptible.

On questioning the patient, it was ascertained that she had inserted two 7.3 grain mercuric chlorid tablets into the vagina to prevent conception.

She was brought to the hospital and was given electric sweat box treatment for rapid elimination, calcium sulphid was given grain for grain, diuretics were given freely, and strychnin hypodermically. Egg albumin by mouth gave no relief. She craved water continually, but would not take nourishment.

Hot water bottles were used with electric heat appliances. The temperature remained subnormal throughout. Urination was scanty, and finally entirely suppressed. There was diarrhea with tenesmus and sanguinolent discharges, and the skin was infiltrated with a dark pigment.

She was easily roused and her mind was clear. Questions were readily answered.

Vaginal examination revealed great tenderness with slight bloody discharge. Not a drop of urine could be obtained within eighteen hours.

The patient died in about twenty-four hours of the time she was brought to the hospital from acute traumatic nephritis.

SURGEON'S MASK FOR THOSE WHO WEAR GLASSES

C. E. LOCKE, JR., SAN FRANCISCO

On entering the operating room, one often sees a surgeon who is being annoyed because his mask does not fit. Especially is the surgeon who wears glasses bothered. If his mask is adjusted to cover the nose, then his glasses soon become so "smoked up" that vision is difficult. The remedy is simple: A narrow strip of adhesive tape is sewed adhesive side up to the upper edge of the mask on its internal side, as shown in the accompanying illustration. This sticks the mask to the bridge of the nose and under the eyes. Thus

Inside of mask: A, adhesive strip (adhesive surface up) sewed to it.

the mask is prevented from sliding, and also the warm breath is prevented from passing upward and condensing on the glasses, rendering them more translucent than transparent. Another more simple method of accomplishing the same result is by the use of a strip with a double face of adhesive tape, such as is made by Johnson and Johnson to secure wigs to the head.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

BARBITAL SODIUM-ABBOTT (See New and Nonofficial Remedies, 1920, p. 84).

The following dosage form has been accepted:

Elixir Barbitol Sodium-Abbott.—Each fluid ounce contains barbitol sodium-Abbott 20 grains.

CHLORAZENE (See New and Nonofficial Remedies, 1920, p. 137).

The following dosage form has been accepted:

Aromatic Chlorazene Powder.—A powder composed of chlorazene, 5 per cent.; sodium bicarbonate, 5 per cent.; eucalyptol, 2 per cent.; saccharin, 1 per cent.; sodium chloride, 87 per cent.

DESICCATED CORPUS LUTEUM-HOLLISTER-WILSON (See New and Nonofficial Remedies, 1920, p. 204).

The following dosage forms have been accepted:

Capsules Corpora Lutea Desiccated-Hollister-Wilson 2 grains.—Each capsule contains desiccated corpus luteum-Hollister-Wilson 2 grains.

Capsules Corpora Lutea Desiccated-Hollister-Wilson 5 grains.—Each capsule contains desiccated corpus luteum-Hollister-Wilson 5 grains.

Tablets Corpus Luteum Desiccated-Hollister-Wilson 2 grains.—Each tablet contains desiccated corpus luteum-Hollister-Wilson 2 grains.

Tablets Corpus Luteum Desiccated-Hollister-Wilson 5 grains.—Each tablet contains desiccated corpus luteum-Hollister-Wilson 5 grains.

DIPHThERIA IMMUNITY TEST (SCHICK TEST) (See New and Nonofficial Remedies, 1920, p. 304).

The Gilliland Laboratories, Ambler, Pa.

Schick Test.—Marketed in packages containing a capillary tube of diphtheria toxin (standardized) and a 5 Cc. vial of physiological solution of sodium chloride for dilution, the amount being sufficient for 20 tests; also marketed in packages containing four capillary tubes of diphtheria toxin and four vials of physiological solution of sodium chloride. Two-tenths (0.2) Cc. of the dilution is injected intradermally which represents 1/50 minimum lethal dose for a guinea-pig of 250 gram weight.

CORPORA LUTEA SOLUBLE EXTRACT—HOLLISTER-WILSON.—A sterile solution of those constituents of corpus luteum which are soluble in physiological solution of sodium chloride containing in each Cc. 0.02 Gm. of soluble matter in addition to sodium chloride, and chlorbutanol as a preservative.

Actions and Uses.—See general article on Ovary, New and Nonofficial Remedies, 1920, p. 201.

Dosage.—1 Cc. daily in extreme cases. Less according to individual cases.

Manufactured by the Hollister-Wilson Laboratories, Chicago.

Ampoules Corpora Lutea Soluble Extract-Hollister-Wilson.—Each ampule contains 1 Cc. corpora lutea soluble extract-Hollister-Wilson.

Corpora Lutea Soluble Extract-Hollister-Wilson is made by extracting desiccated corpus luteum with physiological solution of sodium chloride, and is adjusted to contain 0.02 Gm. of soluble extract in each Cc. The equivalent weight of dried corpus luteum represented by this amount of soluble extract is variable ranging from about 0.06 Gm. to 0.18 Gm.

Corpora Lutea Soluble Extract-Hollister-Wilson is a straw colored liquid with the peculiar odor of corpora lutea.

EUCATROPINE.—Euphthalmine. — Phenyl-Glycolyl-Methyl-Vinyl-Diacetonalkamine Hydrochloride.— $C_6H_5N(CH_3)(C_6H_4CHOH.COO)HCl$ = The 1,2,6,6-tetramethyl-4-mandeloxypiperidine hydrochloride. Eucatropine was first introduced as euphthalmine.

Actions and Uses.—Eucatropine produces prompt mydriasis free from anesthetic action, pain, corneal irritation, or increase in intra-ocular tension. It has little or no effect on accommodation, and such effect as it has disappears more rapidly than with atropine, cocaine, homatropine, etc. In its effects on the general system, eucatropine very closely resembles atropine. It is useful as an aid in ophthalmoscopic examinations in place of atropine, homatropine, etc.

Dosage.—From 2 to 3 drops of a 5 to 10 per cent. solution, according to the age of the patient and the nature of the case, are instilled into the eye.

Eucatropine is prepared by methylating vinyl-diacetonalkamine (M. P. 161 C.) esterifying the methyl vinyl-diacetonalkamine with mandelic acid, treating the free ester in ether solution with gaseous hydrogen chloride, and recrystallizing the precipitated hydrochloride.

Eucatropine is a white, granular, odorless powder; permanent in the air.

Eucatropine is very soluble in water; freely soluble in alcohol and chloroform; insoluble in ether.

Eucatropine melts not below 183 C.

The aqueous solution of eucatropine (1:50) is clear and colorless and is neutral to litmus.

Aqueous solutions of eucatropine (1:50) are precipitated by sodium carbonate test solution, potassium mercuric iodide test solution, iodine test solution, picric acid test solution and many other reagents for the alkaloids.

Add a few drops of nitric acid to about 0.005 Gm. of eucatropine, evaporate the mixture to dryness on a water bath, cool and add a few drops of alcoholic potassium hydroxide test solution together with a fragment of potassium hydroxide. No violet color results (distinction from atropine, scopolamine or hyoscyamine).

Incinerate about 0.5 Gm. of eucatropine, accurately weighed. The ash amounts to not more than 0.1 per cent.

Dissolve about 1 Gm. of eucatropine, accurately weighed, in 10 Cc. of water, make alkaline with ammonia water, shake with successive portions of ether until extraction is complete, washing the ether layer each time with water and adding the washings to the original solution before the next extraction, allow the solvent to evaporate spontaneously, dry the residue to constant weight at 80 C. and weigh. The residue of eucatropine base is not less than 86 per cent.

Recrystallize the free base obtained as above from petroleum ether. The crystals melt at not below 111 C.

Eucatropine-Werner.—A brand of eucatropine complying with the N. N. R. standards.

Manufactured by the Werner Drug and Chemical Co., Cincinnati, Ohio. No U. S. patent or trademark.

Early Diagnosis of Cancer.—Unfortunately the very smallest cancers give no symptoms unless they are on the skin or lip or tongue or elsewhere on the surface of the body, in which situations the earliest diagnoses can be made. Cancers the size of a pea or but a little larger are often diagnosed and removed by a surgeon with an assured favorable result, if the operation has been properly done. In the stomach and internal organs, however, the cancer does not give rise to symptoms until it is quite large, and it is important, therefore, for any one who has any disturbance of the stomach or intestines, loss of weight or anemia, to go at once to a surgeon, because by modern chemical methods and by the use of the roentgen ray, a diagnosis can often be made long before the cancer can be felt or seen. One of the last symptoms of cancer is pain, which is caused by the growth pressing on the nerves as it spreads out through the tissues. —*Health News*, Albany, N. Y., February, 1920.

PROCEEDINGS OF THE NEW ORLEANS SESSION

MINUTES OF THE SEVENTY-FIRST ANNUAL SESSION OF THE AMERICAN
MEDICAL ASSOCIATION, HELD AT NEW ORLEANS, APRIL 26-30, 1920

HOUSE OF DELEGATES

First Meeting—Monday Morning, April 26

The House of Delegates met in the Orleans Parish Medical Society Building, New Orleans, and was called to order at 10 a. m. by the Speaker, Dr. Hubert Work, Pueblo, Colo.

Preliminary Report of the Committee on Credentials

The Chairman of the Committee on Credentials made a preliminary report for this committee, stating that the committee desired at this time to report progress, and that more than a quorum of delegates had qualified.

As there was no objection, the report was accepted.

Next in order was the roll call by the Secretary.

The Secretary stated that the registration of the delegates in attendance recorded the presence of more than a quorum.

A quorum being present, the Speaker announced that the House was constituted and ready for the transaction of business.

The next order of business was the presentation, correction, and adoption of the minutes of the Seventieth Annual Session.

The Secretary stated that the minutes had been printed and circulated among the members of the House of Delegates, with the request for criticisms or corrections, but none had been received.

It was moved that the reading of the minutes of the Seventieth Annual Session be dispensed with and approved as printed.

Seconded and carried.

Addresses of Executive Officers

Drs. Hubert Work, Speaker; Alexander Lambert, President, and William C. Braisted, President-Elect, addressed the house. See addendum.

Reports of Officers

Report of the Secretary

To the Members of the House of Delegates of the American Medical Association:

The following report for the year 1919-1920 is respectfully submitted:

MEMBERSHIP

The membership of the various constituent state associations which is the membership of this Association, according to records in the Secretary's office, April 1, 1920, was 83,338, as shown in the accompanying table.

FELLOWSHIP*

The Fellowship of the Scientific Assembly of the American Medical Association on May 1, 1919, was 45,412. During the year 477 Fellows have died, 123 have resigned, 171 have been dropped as not eligible, 303 have been dropped for nonpayment of dues, and the names of ten have been removed from the rolls on account of being reported "not found," making a total of 1,084 names to be deducted from the Fellowship roll. There have been added to the Fellowship roll 3,307 names of which 2,136 were transferred from the subscription list of THE JOURNAL. The Fellowship of the Association on

April 1, 1920, was 47,045, a net increase for the eleven months covered by this report of 1,633.

This gain in the number of Fellows, as in previous years, is due largely to circularizing subscribers to THE JOURNAL who are eligible to Fellowship, urging them to become Fellows.

DEATHS OF OFFICERS

During the year, two of the officers of the Association have died:

Dr. Emery Marvel, Atlantic City, N. J., Second Vice President, died in Philadelphia following a surgical operation, Jan. 8, 1920. Dr. Marvel was the chairman of the Local Committee on Arrangements for last year's annual session.

Dr. Elmer Ernest Southard, Cambridge, Mass., chairman of the Section on Nervous and Mental Diseases, died in New York City on Feb. 8, 1920, after a brief illness.

INTERIM APPOINTMENT

Early last fall, Dr. J. B. Blake, Boston, resigned as a member of the Council on Scientific Assembly, and the President appointed Dr. Frank P. Gengenbach, Denver, to serve on this council until this annual session.

ORGANIZATION

In my report submitted at the last annual session, a comment was made relative to the activity of the Association in assisting those physicians who had been in military service to resume civil practice, and it was stated that the almost universal opinion was that these physicians were finding a hearty reception in the localities where they formerly practiced, and that where they had elected to locate in new communities, they were in practically all instances welcomed by the medical profession. Attention was called to the task which confronted the Association along with its constituent state associations and their component societies to assist in bringing about a better state of affairs in the medical profession. It is gratifying to report that since the 1919 annual session, the organized medical profession has met the obligation which was then anticipated, and that in large part the members of the Medical Reserve Corps have again taken up civil practice.

There are, however, new obligations somewhat similar in character which must be undertaken. As noted last year, it cannot be expected that an exact prewar status will ever be restored. There are new economic and civil relationships affecting every calling which have and will develop during the reconstruction period. All of these are of peculiar interest to the individual practitioner both in his personal and family relationships and in his ability to serve the public. In all these questions, the American Medical Association, as the inclusive nonsectarian organization of practitioners of medicine of the United States, must have an active interest, and must give its best endeavor to the solution of the problems involved. Many of these will command the attention of the House of Delegates, and where it is advisable investigations should be directed to be conducted by the several Councils of the Association so that when the House of Delegates next meets, it shall have at hand data which will warrant the determining of the policy of the Association in these various matters.

In order that the Association shall be able to cope with these problems, it is advisable to strengthen our organization wherever this is possible. Not only should the various branches of the organization—the county, state and the national—put forth earnest efforts to increase membership, but a concerted effort should be made to attain a closer and more intimate cooperation between these branches. There is a possible danger which should be guarded against

* These figures do not include those who are still Fellows of the Scientific Assembly by virtue of their being commissioned and on active duty as Medical Reserve Corps Officers, but who, previous to their military service, were not Fellows.

—namely, a multiplicity of organizations in the same territory having practically the same objective. Whenever an unnecessary new organization in an already occupied territory is effected, there is always the danger that rivalry will result between the two organizations which consciously or unconsciously will interfere with the effectiveness of the organization of the medical profession in that locality. In a few instances, new organizations of this character have

diverted from the county and the state branches of the Association the activities of certain members who previously had taken a leading part in county and state work, and it has been proposed even that financial support should be given to certain of these new bodies in a manner which might deprive the branches of the American Medical Association of the benefits of funds which, if available, could be used best through the regular channels of the state and county organizations. It is, of course, recognized that the American Medical Association and its several branches, as well as these newer organizations, are purely voluntary organizations. No one can be compelled to hold a membership which he does not desire, nor should he be forced to withdraw from or refuse to join any other organization in order that he may maintain his membership in a component branch of the American Medical Association. Nevertheless, it seems advisable to submit this matter to the House of Delegates in the hope that the members will give careful consideration to the advisability of strengthening the organization wherever this is possible, and that the question in turn may be brought to the attention of the state associations and the county societies, and that in all branches of the organization, members of the medical profession shall be urged to devote themselves to the advancement as well as the extension of the county, state and national bodies.

Other matters in which the office of the Secretary has been active, are reported to the House of Delegates from other sources.

Respectfully submitted,

ALEXANDER R. CRAIG, Secretary.

Report of the Board of Trustees

Dr. Philip Marvel, Chairman, presented the following report, which was referred to the Reference Committee on Reports of Officers.

To the Members of the House of Delegates of the American Medical Association:

In these times of unusual political and social unrest, with the general dissatisfaction accompanying high cost of living, it is a pleasure to be able to report that the various activities of the Association are progressing satisfactorily and that so far as THE JOURNAL is concerned the year has been one of the most satisfactory in its existence.

The detailed statement which appears in tabular form in the addenda will show that there were 3,760,351 copies of THE JOURNAL printed in 1919—265,504 more than during the previous year—and that the average weekly circulation was 72,314. On January 1 the actual circulation was 74,919; this number does not include extra, sample or special copies that were sent out week by week. THE JOURNAL mailing list on Jan. 1, 1920, as compared with January 1 of the preceding year shows an increase of 7,375; that is to say, there was an increase of over 7,300 in the circulation of THE JOURNAL during the year 1919—a remarkable showing considering all the conditions.

ADVERTISING DEPARTMENT

The advertising department makes an unusually good showing: this is due partly to the amount of advertising space sold, but more particularly to increased advertising rates. Naturally, the larger the circulation of a periodical the more valuable it becomes as an advertising medium and the higher is the rate for advertising space it commands. However, the past year has been one of great prosperity, and business firms have been very liberal in advertising. This must be kept in mind in planning for the future. It is needless to add that we are keeping our advertising up to the standard which has prevailed for many years; that if we cared to lower this standard there might be still a larger increase in the advertising income.

SPANISH EDITION

The first year of the Spanish Edition of THE JOURNAL has been reasonably satisfactory. Its publication was undertaken with some hesitancy because it meant a venture in an entirely

* Not including Fellows of American Medical Association.

Note.—The number of members of the different associations stated in this table is in accord with the membership of the several associations as they were reported to the Secretary on April 1, 1920.

The lack of an effective uniform system for reporting the membership of the state associations accounts for whatever discrepancies this table shows and detracts from the value of the statement.

Component societies are those societies which compose the state association. A component society may include one county or more.

1. The state of Maryland has 23 counties and the city of Baltimore; Missouri has 114 counties and the city of St. Louis.

2. These state associations are divided into district societies, and these are listed in the table as component societies. Some of these districts are smaller and some larger than the county, the county lines being ignored.

3. Provision is made for the physicians in each of these counties to join the component society in an adjoining county.

4. Virginia has recently adopted the plan of organization and is now establishing component county medical societies.

5. This figure includes the Medical Corps of the Army, the Navy and the Public Health Service.

new field. Other periodicals had been published in this country in the Spanish language for circulation in South and Central America, but their publication was undertaken for commercial reasons. Our Spanish Edition entered the field solely as a scientific periodical for educative and scientific purposes, and it has been received with approbation. The field was a difficult one to work in the first place because there was not available any physician's directory, or any even fairly reliable list of physicians of standing. However, a list of such physicians has been gradually assembled so that now there is a fairly reliable one at the Association headquarters. Included in this list are the physicians of Central and South America and the Philippine Islands.

Another difficulty has been the mailing facilities; these have been anything but satisfactory. Under normal conditions it takes a long time for a communication to reach the South American countries, with the exception of those bordering on the Gulf of Mexico.

At the end of the year the subscription list comprised 2,908 names. To those who appreciate the difficulties and know the conditions that prevailed at the beginning, this must be regarded as quite satisfactory. Roughly, this circulation is as follows: The largest number of subscribers naturally are in Mexico—539; Cuba next, 530; Argentina, 270; Brazil, 194 (in Brazil Portuguese is the language in general use, therefore it is rather remarkable that this number of subscribers has been secured there); Chile, 179; Spain, 142; Peru, 101. The rest of the circulation is in Bolivia, Colombia, Costa Rica, Ecuador, Guatemala, Honduras, Nicaragua, Paraguay, Salvador, Santo Domingo, Uruguay, Venezuela, Panama and Porto Rico.

It is not to be expected that this journal could be published without a loss for the first few years. As will be remembered, the venture was undertaken at the request of the International Health Board of the Rockefeller Foundation, which agreed to pay half the loss. It should be explained in this connection that the number of copies of each issue printed was 4,500 to 5,500, and that the excess above those subscribed for was sent out as sample copies. Hereafter, of course, there will be fewer sample copies distributed; consequently a less expense with an increased income. During the months of January, February and March the circulation has been steadily increasing. The actual loss to the Association to date has been less than \$10,000, which amount promises to be returned with more than gratifying results within the first five year period of its publication.

ARCHIVES OF INTERNAL MEDICINE

The ARCHIVES OF INTERNAL MEDICINE has made a good showing for the past year. On December 31 there were 2,593 subscribers—seven less than the previous year. This decrease was due to the fact that the government, which during the war had taken a large number of copies, had since cut down its order considerably. There was actually an increase of 227 in our domestic list, and of forty-five in the foreign list.

A reference to the auditor's report will show that this journal made a net gain last year of \$1,692.82, as compared with a loss the previous year of \$1,320.58. This better showing is explained in part by the fact that the two volumes for 1919 were smaller than in previous years, and in part also by the increased subscription price. Previous to last year the regular price was \$4 per annum, but if taken in combination with one or more of the other Association periodicals only \$3. The price at the present time has been made \$5, and the combination price \$4. Last year there were only 217 subscribers who paid the full \$5 rate.

AMERICAN JOURNAL OF DISEASES OF CHILDREN

The AMERICAN JOURNAL OF DISEASES OF CHILDREN likewise made a very satisfactory showing: On Jan. 1, 1920, there were 2,531 names on the mailing list—an increase of 417 over January 1 of the previous year—and the auditor's report shows a gain of \$784.37, as compared with a gain of \$404.62 in 1918. In this journal, the number of pages for 1919 was much increased over that of the previous year.

The subscription price was also increased from \$3 to \$4, but here again practically all the subscribers get it at the club rate of \$1 less than the regular price.

ARCHIVES OF NEUROLOGY AND PSYCHIATRY

None of the other special journals published by the Association seems to have given more satisfaction or to have been more appreciated by the specialists for whom it is published than the ARCHIVES OF NEUROLOGY AND PSYCHIATRY. The circulation on Jan. 1, 1920, was 1,158. Considering the special character and the limited number of men to whom such a journal will appeal, this circulation in a year is phenomenal; it is larger than that of any other journal devoted to these subjects in any language.

Naturally a loss might have been expected, but the loss as shown in the auditor's report—\$2,695.40—is greater than it should be, and indicates that, considering the size of the publication, the number of pages (the two volumes for 1919 contained 1,546 pages), the number and character of the illustrations—many being in colors—the original price of \$5 was too low, especially as the subscribers, with very few exceptions, pay \$1 less than the regular price in combination with other journals. The price of this periodical will, therefore, be raised from July 1 to \$6, which means \$5 in combination with any other of the Association's publications.

ARCHIVES OF DERMATOLOGY AND SYPHILOLOGY

In January we commenced the publication of the ARCHIVES OF DERMATOLOGY AND SYPHILOLOGY, which has started out very well.

ARCHIVES OF SURGERY

It is proposed to commence the publication of the ARCHIVES OF SURGERY in July. It is now planned to publish this at first as a bimonthly; later, as the amount of material increases, it will become one of the monthly publications.

PUBLICATION OF SPECIAL JOURNALS

The Constitution states that the object of the American Medical Association is to promote the science and art of medicine. The Trustees are of the opinion that there is no better way of doing this than by aiding the various scientific workers in the publication of their contributions. The Association is unusually well equipped mechanically to do the printing; and its facilities for direct contact with the profession make possible the promotion of these publications in an economic manner. This undoubtedly is being thoroughly appreciated, for other special groups are beginning to look to the Association to help them out in the publication of their special periodicals. For instance, an appeal from a large number of physicians was received by the Trustees urging the Association to publish a journal to take the place of the *American Journal of Obstetrics and Diseases of Women and Children*. The present condition of our printing plant is such, however, that it does not seem advisable to attempt the publication of any more journals for a while.

While the Trustees favor the publication of these journals by the Association they feel that they should not be published at a loss, but rather at cost or at slightly above cost.

QUARTERLY CUMULATIVE MEDICAL INDEX

This is another of the scientific publications of the Association, of which the Association should be proud. The circulation at the end of the year was 738—an increase of only 88 during the year. However, no effort has heretofore been made to push the circulation of the INDEX. From now on and until the scientific men of our profession know that there is such a help for research workers at a nominal price, more effort will be made to increase the circulation.

The INDEX last year sustained a loss of \$1,787.12. Here again we realize that the price is lower than it should be, and after July 1 there will be an increase of \$1, making it \$5 per annum. Those who know the book appreciate the fact that this is an extremely low price for one of its kind. It could not be published without a greater loss if it were not for our splendid facilities.

COOPERATIVE MEDICAL ADVERTISING BUREAU

This Bureau is no longer an experiment, it is a great success; it is so regarded, we believe, by all the state journals it represents, which means by all the state journals except that of Illinois. It has now become self-supporting, and at the end of 1919 it was possible to rebate a considerable sum to the journals represented, as was done at the end of 1918.

As we have stated in our former reports, the Bureau has demonstrated that it is possible to secure for these journals a fair amount of advertising of which neither the journals themselves nor the medical profession need be ashamed. The Bureau has removed the temptation to accept that class of advertising which for so many years had been not altogether creditable.

COUNCIL ON PHARMACY AND CHEMISTRY

In reply to the suggestion made last year by President Bevan that there should be closer cooperation between the large pharmaceutical houses and the Council on Pharmacy and Chemistry, the Council has submitted to the Board of Trustees the following statement:

"COOPERATION OF THE PHARMACEUTICAL HOUSES: At the opening meeting of the House of Delegates last year, President Arthur Dean Bevan suggested the desirability of greater cooperation between the large pharmaceutical houses and the Council on Pharmacy and Chemistry. The need of such cooperation has been recognized by the Council from the first. In no one direction has the Council made greater effort than in its endeavor to secure the fullest cooperation of the various pharmaceutical houses. The difficulty has been, and always must be, the fundamental antagonism between objectives that are largely commercial on the one hand and purely scientific on the other. Nevertheless, the Council has always believed—and has acted on the belief—that there is a possible middle ground wherein the interests of therapeutics would not be injured but would go hand in hand with a commercial development based on enlightened self interest.

"The profits to be made by a pharmaceutical house from the sale of a staple drug—a pharmacopeal, National Formulary, or nonproprietary preparation—which enters into free competition with other drugs of the same kind, are moderate; the profits to be made from the sale of a proprietary medicine on which the manufacturer holds a monopoly are usually large—sometimes enormous. There are, broadly, two kinds of proprietary preparations advertised to physicians: One represents laborious research ending in the production of a new medicinal chemical; this product can be patented and the manufacturer can obtain a seventeen-year monopoly on its manufacture and sale. The other represents no research but comprises simple mixtures—frequently of the "shotgun" variety—of well known pharmaceuticals, or biologic products sold under trade names. As these do not represent anything new or original the manufacturer is unable to obtain a patent, but by means of the trade name he can and does obtain a perpetual monopoly. This, from a business standpoint, is more valuable than the limited monopoly granted by a patent. It is not surprising that proprietary remedies of the latter type flourish so long as physicians unthinkingly accept and prescribe them solely on the manufacturer's valuation.

"The Council has practically the undivided support of manufacturers of medicinal chemicals; that is, of proprietaries of the first mentioned type. But pharmaceutical firms which have found it profitable to promote proprietaries of the second type—"specialties," unscientific or ordinary mixtures of pharmaceuticals or biologic products sold under trade names—have not supported the Council.

"When the Council was organized, it was hoped and believed that all the large pharmaceutical houses would find it possible and desirable, if not actually more profitable, to shape their business methods so as to make their proprietary and other articles conform to those conservative standards on which the Council bases its rules, and thus render such articles acceptable for New and Nonofficial Remedies. It soon developed, however, that the methods of the pseudochemical companies, whose sales propaganda in the interest of unscientific nostrums with its attending damage to scientific medicine had led to the establishment of the Council, had found their lodgment in most of the pharmaceutical houses. It was a genuine disappointment to the Council to find that some of the large and old-established firms were not only unwilling to cooperate with the Council, but in many instances exhibited a definite antagonism to the Council's work.

"The object—and duty—of the officers of pharmaceutical houses is primarily to pay dividends to their stockholders. Through skillful advertising or the persuasiveness of "detail men," they are able to induce physicians to prescribe their controlled products, on which there are large profits, even though such products have not only not been accepted by the Council, but, in many instances, have been disapproved. Is it any wonder that concerns which put out such products are indifferent or openly antagonistic to the work of the Council? The matter is largely one of business policy. When the medical profession as a unit will support the Council in its work, then such firms will find it good business policy to accede to Dr. Bevan's suggestion—but not before."

Evidently the problem resolves itself into this: The Council, constituted of scientific men, working without remuneration in the interest of scientific medicine and the medical profession, expects—and rightfully—the cooperation and support of the members of that profession. What is needed,

therefore, is the active, sympathetic cooperation of physicians; the cooperation of pharmaceutical houses will follow as a matter of course.

THE PROPAGANDA DEPARTMENT

The interest of the profession and the public in the work of the Propaganda department is increasing. During the past year the department has received more inquiries from newspapers regarding medical "copy" than ever before, and has also had an unusually large number of inquiries relative to itinerant quacks. Data were furnished which, in many instances, sufficed to bring action that materially protected the public; in some instances the information was used as the basis of legal action against the quacks. The department also has answered a remarkably large number of inquiries from schools and colleges, due to the attention that teachers are giving to the nostrum evil, and to the knowledge they have of the availability of the Propaganda department's educational material. More than the usual number of inquiries has been received regarding those "patent medicines" whose most potent ingredient is alcohol. The pamphlets, educational posters and stereopticon slides that are prepared and issued by the Propaganda department continue in active demand. One of these pamphlets was considered of sufficient importance to be introduced into the records of a government committee that was considering a bill designed to restrict advertisements relating to the treatment of venereal diseases and of certain sexual disorders. A new edition of "Nostrums and Quackery" is in the hands of the printers and will be issued shortly. This department of THE JOURNAL continues to justify its existence. As a clearing house for information on the subjects with which it deals it proves a boon alike to the profession and the public.

INCREASED EXPENSES

The steadily increasing cost of production is likely to cause serious concern if it continues much longer. As an illustration we might refer to the price of paper used in THE JOURNAL. A reference to the auditor's report for 1918 will show that paper for THE JOURNAL that year cost approximately \$162,000. Last year—1919—it was over \$217,000—an increase over the preceding year of approximately \$55,760. There was an increase in circulation, but this was small as compared with the increase in cost of paper. We entered this year with a still further increase; at the lowest estimate, our paper for the current year will cost in the neighborhood of \$35,000 more than last year, even though there should be no further increase. Wages in the printing trade are still advancing; an increase that went into effect last February, 1920, adds at least \$22,000 to the pay in the printing department. The increase in these two items alone—paper and labor in the mechanical department—will add at least \$57,000 to the expense this year. In addition there is a steady increase in the wages for all the other help—stenographers, typists, clerks, etc.

While there is no immediate cause for anxiety it is well for us to realize that we must be prepared for whatever the future may have in store. It may be necessary either to increase the subscription price of THE JOURNAL—say \$1.00 a year—or to reduce its size. However, this is for the future. Your attention is called to these matters that you may know the conditions that have developed and which are developing.

HOSPITAL STANDARDIZATION

At the meeting of the Association in Atlantic City in 1919 the House of Delegates adopted the following resolution, which was presented by the Reference Committee on Reports of Officers:

"That the Trustees be instructed to establish a Council on Hospitals as an independent body, or a Bureau on Hospitals as a body subsidiary to one of the already existing councils, the details of the organization to be left to the Trustees with power to act."

In reference to this action of the House of Delegates the Board desires to place before you the following facts: For

many years the work of the Council on Medical Education has necessarily embraced the accumulation of data relating to hospitals. This phase of the Council's work gradually increased in importance to a degree that two years ago it was found necessary to create in the office a special section on hospitals—which, in reality, is a bureau of the Council on Medical Education—having hospital work particularly in charge. The efficient secretary of the Council on Medical Education has directed this work both before and since the bureau was established. During the last seventeen years a vast amount of valuable information concerning the hospitals of the country has been obtained by means of personal inspection, correspondence, answers to questionnaires sent to members of attending staffs, officers and ex-interns of hospitals, and in this work the secretary has sought and obtained the splendid cooperation of the component county and state medical societies. The data so obtained have been recorded, indexed and filed in the office of the Association, and have been the basis of the lists of hospitals published in the directory, and lists of hospitals approved for intern training which, since 1914, have been widely distributed. The character and the great utility of the data on file are further shown in the reports of the Council on Medical Education to the House of Delegates for the last several years, and particularly in the reports for 1919 and for this year.

Your attention is directed also to the fact that the standardization of hospitals is intimately related to medical education. The extensive means within the jurisdiction of the Association, which may be utilized to advance and maintain the standards of medical education, may be, and in fact are being used coincidentally to standardize hospitals. These means include those resources of the Association embraced in its organized personnel and well-equipped office, its many and varied files and indexes of information relating to the medical profession, and its command of the cooperative influence of its membership as represented in the constituent state and county societies—resources which make unnecessary the expenditure of extremely large sums of money.

In this connection your attention is directed to the fact that, comparatively speaking, the Association has never spent a large sum of money annually for the standardization of medical education. The great things accomplished have come about through the sentiment created in the public mind through annual conferences and by the publication of statistics relating to medical education and business and the resultant support of the members of the Association of the policies, educational standards and classifications put forward by the Council on Medical Education.

Experience has shown that work worth while, such as has been accomplished by each of the various Councils of the Association, has depended largely on one man. With no desire to belittle the splendid advice and assistance of the members of a Council who are responsible to the Association for the adopted policies, minimum standards of work and methods of procedure, after all the real responsibility for efficiently carrying out the program and for the collection and compilation of the accumulated data rests chiefly on its secretary acting with the related personnel of the Association headquarters under the direction of the General Manager.

Therefore we are of the opinion that the work which the Association may most efficiently and fruitfully carry on in the standardization of hospitals is provided for in the bureau already created in the office and under the jurisdiction of the Council on Medical Education. This opinion is justified also by the fact that the present industrial unrest with the increasing cost of labor, in all departments, the high price of the necessities of life and of the materials needed in productive commercial pursuits, demand the utmost economy, consistent with efficient production in the management of the affairs of the Association.

In conformity with the statements made above, the Board of Trustees recommends to the House of Delegates the change in name of the "Council on Medical Education" to the "Council on Medical Education and Hospitals." In view

of the fact that no existing organization has the legal power to standardize hospitals, the Board recommends that the House of Delegates direct the Council on Medical Education to substitute the term of "approved hospitals" for that of "standardized hospitals" in its official reports and publications.

In the addenda are statistics in tabular form covering the circulation of THE JOURNAL, etc.; the treasurer's statement, and the complete auditor's report. No reference is here made to the work of the various councils—the Council on Health and Public Instruction, the Council on Scientific Assembly, the Judicial Council and the Council on Medical Education—as these Councils will make complete reports direct to the House of Delegates.

Respectfully submitted,

FRANK BILLINGS.	A. R. MITCHELL.

PERCENTAGE OF PHYSICIANS RECEIVING THE JOURNAL

The following table gives the number of physicians in the United States (based on the sixth edition of the American Medical Directory), the number receiving THE JOURNAL, and the approximate percentage in each state. It does not include copies sent to physicians in the United States Army, the United States Navy or the Public Health Service:

State	Number Receiving JOURNAL	Physicians in State 6th A. M. Dir.	Approx. Percentage 6th A. M. Dir.
Alabama	758	2,530	29
Arizona	262	333	78
Arkansas	638	2,587	25
California	3,491	5,929	61
Colorado	979	1,713	57
Connecticut	1,071	1,701	63
Delaware	129	264	49
District of Columbia...	639	1,237	51
Florida	510	1,296	39
Georgia	1,084	3,442	31
Idaho	239	458	52
Illinois	6,961	11,095	62
Indiana	1,894	4,765	39

State	Number Receiving JOURNAL	Physicians in State 6th A. M. Dir.	Approx. Percentage 6th A. M. Dir.
Iowa	2,037	4,004	50
Kansas	1,230	2,668	46
Kentucky	1,102	3,483	31
Louisiana	786	2,060	38
Maine	481	1,179	40

Virginia	1,068	2,552	42
Washington	881	1,698	52
West Virginia	764	1,759	43
Wisconsin	1,703	2,817	60
Wyoming	151	254	60

The number of Fellows and subscribers on THE JOURNAL mailing list each year since, and including, 1900, is indicated below. Libraries, colleges, advertisers, exchanges, etc., are not included:

Year	Fellows	Subscribers
January 1st, 1900	8,445	4,633
January 1st, 1901	9,841	8,339
January 1st, 1902	11,107	10,795
January 1st, 1903	12,553	12,378
January 1st, 1904	13,899	14,674
January 1st, 1905	17,570	15,698
January 1st, 1906	20,826	17,669
January 1st, 1907	26,255	20,166
January 1st, 1908	29,382	20,880
January 1st, 1909	31,999	18,983
January 1st, 1910	33,032	19,832
January 1st, 1911	33,540	20,504
January 1st, 1912	33,250	21,620
January 1st, 1913	36,082	19,863
January 1st, 1914	39,518	19,751
January 1st, 1915	41,254	20,430
January 1st, 1916	41,938	22,921
January 1st, 1917	42,744	22,156
January 1st, 1918	43,420	23,117
January 1st, 1919	42,366	24,687
January 1st, 1920	44,340	30,032

During 1919 there were transferred to Fellowship 2,118 from the subscription department, and 20 from THE ARCHIVES OF INTERNAL MEDICINE, THE ARCHIVES OF NEUROLOGY AND PSYCHIATRY and the AMERICAN JOURNAL OF DISEASES OF CHILDREN—a total of 2,138. Four hundred and twenty-one were discontinued as Fellows, but continued as subscribers.

TREASURER'S REPORT

Report of the Treasurer of the American Medical Association for the year ended December 31, 1919.

ASSOCIATION RESERVE FUND

Reserve Fund as at December 31, 1918	\$208,727.38
Investments	63,242.75
Interest—Bonds	\$10,959.96
Interest—Uninvested	256.33
	11,216.29
Reserve Fund as at December 31, 1919	\$283,186.42
Balance as at December 31, 1919	\$ 265.34

TREASURER'S GENERAL ACCOUNT DAVIS MEMORIAL FUND

Balance as at December 31, 1918	\$ 3,651.80
Interest received for the year	110.36
Balance as at December 31, 1919	\$ 3,762.16

AUDITORS' REPORT

CHICAGO, January 19, 1920.

To the Board of Trustees,
American Medical Association, Chicago, Illinois.

Dear Sirs:

In accordance with your instructions, we have audited the accounts of the American Medical Association for the year ended December 31, 1919, and now submit our report thereon.

SURPLUS ACCOUNT

The surplus at the beginning of the year amounted to \$471,661.50, and the surplus at the end of the year amounted to \$456,839.39, a decrease of \$14,822.11, which may be accounted for as follows:

Transfer to Reserve Fund	\$ 63,621.71
Less Net Gain on Operations	48,799.60
Net Decrease in Surplus	\$ 14,822.11

The net decrease in surplus is spread over the assets and liabilities as follows:

Decrease in Assets:	
Current Working Assets (Increase)	\$ 11,683.64
Prepaid Expenses (Decrease)	1,713.69
	\$ 9,969.95
Less Decrease in Property and Equipment	20,908.89
	\$ 10,938.94
Add Increase in Liabilities:	
Advance Payments on Publications	\$ 3,524.63
Increase in Accounts Payable	358.54
	3,883.17
Net Decrease in Surplus as above	\$ 14,822.11

FINANCIAL POSITION

The financial position of the Association as at December 31, 1919, is shown in the following statement:

BALANCE SHEET AS AT DEC. 31, 1919.	
ASSETS:	
Property and Equipment at Cost, less Depreciation:	
Real Estate and Buildings	\$209,109.68
Machinery	48,850.62
Type and Metals	7,577.81
Furniture and Equipment	13,843.63
Chemical Laboratory	1,650.26
Library	817.95
	\$281,849.95
Reserve Fund Investment	283,186.42
Current and Working Assets:	
Inventory of Materials, Supplies and Work in Process	\$52,621.41
Accounts Receivable:	
Advertising	\$39,544.94
Cooperative Medical Advertising Bureau	5,633.36
Reprints	2,738.24
Miscellaneous	63,407.96
	111,324.50
Directory	510.54
Cash in Bank and on Hand	24,788.77
	\$189,245.22
Prepaid Expenses:	
Insurance	\$ 611.31
Session — 1920	293.19
	904.50
Total	\$755,186.09
LIABILITIES:	
Accounts Payable:	
Cooperative Medical Bureau	\$ 6,736.23
Sundry	112.87
	6,849.10
Advance Payments on Publications	8,311.18
Association Reserve Fund	283,186.42
Surplus	456,839.39
Total	\$755,186.09

The balance sheet submitted, in our opinion, correctly reflects the financial position of the Association as at December 31, 1919, subject to provision for accrued interest, taxes and "Journal" subscriptions paid in advance, less subscriptions and memberships due and unpaid.

We examined the securities representing the investment of the Association Reserve Fund, and found them in order.

We verified the cash on hand by actual count and the cash in bank by certificates obtained from the Association's bankers. The following is a statement of the cash balances:

Continental and Commercial National Bank	\$ 21,331.06
First Trust and Savings Bank (Treasurer's Account)	265.34
Cash on Hand	3,042.37
Cashier's Fund	150.00
Total	\$ 24,788.77

OPERATIONS

The operations of the Association for the year ended December 31, 1919, are shown in the following statements:

INCOME AND PROFIT AND LOSS ACCOUNT FOR THE YEAR ENDED DECEMBER 31, 1919	
JOURNAL:	
INCOME:	
Fellowship Dues and Subscriptions.....	\$357,684.78
Advertising	395,598.38
Jobbing	13,291.14

The audit embraced an exhaustive test of the various sources of income and the verification of the cash disbursements with proper vouchers on file.

We are pleased to report that we found the accounting records to have been kept in the usual good order and that every facility was afforded us for the proper conduct of the audit.

Yours truly, MARWICK, MITCHELL, PEAT & Co.

Report of the Judicial Council

Dr. M. L. Harris, Illinois, Chairman, presented the report of the Judicial Council, which was referred to the Reference Committee on Report of Officers:

To the Members of the House of Delegates of the American Medical Association:

There have been no questions referred to the Council for adjudication during the past year. The two matters remaining in the hands of the Council from the last House of Delegates are the revision of the Constitution and By-Laws, and the further consideration of the feasibility of establishing some system of old age or invalidity insurance for members of the profession.

The Constitution and By-Laws as revised are herewith submitted.¹ At first glance it may seem that many radical changes have been made, but on closer investigation it will be found that such is really not the case. During the past few years of the evolutionary development of the Association, quite a number of changes have taken place in the character of the work done as well as in the manner of doing it, and some of these changes, although fully recognized, have not been clearly set forth in the By-Laws.

The Constitution, likewise, has failed to state correctly the character and form of the organization. The opportunity has been taken, therefore, to define the organization as it really is and has been since the reorganization in 1901. It will be noted that the verbiage has been changed in many places for the purpose of clarification and to eliminate ambiguity and duplications, but on comparison it will be found that there have been no changes made in principles or fundamentals.

Taken up more in detail, the first change noted in the Constitution is in the definition of the organization. The word "federacy," as defined in the American Dictionary and Cyclopedia, expresses correctly the character of the organization; hence this word has been used in defining it. Since the reorganization the Association has been a federacy, yet the fact has never been clearly set forth in the Constitution.

The objects of the Association have been expressed in the broadest and simplest manner possible. By omitting to mention a few of the things contained in the old Constitution under the title "Objects," we do not by implication eliminate a great many more things which the Association may do but which are not mentioned. In defining the objects of an association such as this, it is desirable to state them as briefly and as broadly as possible. The constituent associations and component societies are defined and the difference between members of the American Medical Association and Fellows of the Scientific Assembly made clear. The composition of the House of Delegates, together with its powers, are set forth, and the general officers of the Association defined.

There have been no material changes in the Scientific Assembly or the sections. No changes have been made in the section on "Funds," except to shorten it up slightly; likewise no changes in the method of amending the Constitution.

Concerning the By-Laws, it will be found that many paragraphs which were but duplications have been eliminated; likewise some sections which were already set forth in the Constitution and hence were but repetitions. Most of these are apparent at a glance, and as they add nothing to nor take anything from the present By-Laws, need not be further elaborated. There have been some changes made in the verbiage without changing the sense where it seemed that by so doing the meaning could be clarified.

As there are many points which are common to all of the standing committees or councils, these have all been grouped

1. These appear in the official handbook of the House of Delegates.

together to save repeating them under each council, thus materially shortening the sections on councils.

Much thought has been given to rewording the Constitution and By-Laws and it is felt that the changes made correctly express the conditions as they exist and that these instruments are now brought up to date.

OLD AGE AND INVALIDITY INSURANCE

During the past year the Council has been collecting data on the subject of old age and invalidity insurance for members of the association. A brief questionnaire was sent to the secretary of every county medical society in the organization. The questionnaire asked for information as to the number of physicians in the county dependent on financial aid and as to how many of that number were members of the county medical society: the number over 65 years of age dependent because of age, with the age of each, if known; and the number under 65 dependent because of physical disability, with the cause of physical disability, if known. Reports were received from every state in the Union, and the reports covered 53.48 per cent. of the total number of physicians in the entire country, or 77,083 of the 144,116, the estimated total number of physicians in the country. One hundred and fifty-six were reported to be dependent on financial aid; 120 on account of old age, and thirty-six on account of physical disability. Only 42,824 of the 77,083 physicians reported on are members of the American Medical Association, and of this number seventy-seven or less than 0.2 per cent. were dependent. This gives an estimated number of 146 dependents out of a total membership of 81,239. There were no dependents reported in twenty-eight states, including the District of Columbia. Georgia heads the list with the largest number, namely sixteen out of 896 reported on, or 1.78 per cent. Rhode Island's report covered 100 per cent. of the members, while that of New York covered only 23 per cent., statistics from the city not being obtainable.

In studying these statistics, as incomplete as they may be, one is impressed with the remarkably small number of dependent physicians. It is quite likely that the number of physicians over 65 and unable to practice by reason of age and who have not been able to save a competence for their old age is much greater than that stated, but they are living with members of the family and hence not dependent on charity. The number under 65 who are dependent by reason of physical disability likewise seems rather low, and no doubt a more searching inquiry would increase the number of dependents due to old age as well as to physical disability. As so many of the states failed to report any dependents, even where a majority of the members were covered by the report, it would seem to the Council that the question of rendering financial aid should rest with the state organization and be treated as a local matter.

Respectfully submitted,

M. L. HARRIS, Chairman,	RANDOLPH WINSLOW,
I. C. CHASE,	WILLIAM S. THAYER,
H. A. BLACK,	A. R. CRAIG, Secretary.

Report of the Council on Health and Public Instruction

Dr. Victor C. Vaughan, Michigan, Chairman, presented the report of the Council on Health and Public Instruction, which was referred to the Reference Committee on Reports of Officers.

The report follows:

To the Members of the House of Delegates of the American Medical Association:

ACTIVITIES DURING THE YEAR

Owing to the early date of the meeting this year, the time covered by the Council report is from May 1, 1919, to March 1, 1920, a period of ten months.

REORGANIZATION OF FEDERAL PUBLIC HEALTH ACTIVITIES

In its report for 1919, the Council stated that one of the more urgent needs in the present public health situation was

increased knowledge regarding organized and official public health activities as a basis for constructive legislation. This is a work for which the Council is especially well fitted. In its report for 1914, the Council said, regarding the need of a careful study of the public health work of the federal government with a view to determining exactly what the federal government is doing and can do for public health: "The need for such an investigation hardly needs more than to be stated. The American Medical Association stands unreservedly pledged to the securing at the earliest possible moment of an adequate national health organization. In the discussion of this subject . . . a lack of accurate and complete information regarding present health activities on the part of the federal government has been apparent. Extreme claims have been made on both sides, one set of advocates asserting that the United States government was doing more for public health than any other national government in the world, the other asserting that practically nothing was being done by our government which could compare with the health activities of European nations. Such a condition is not credible to a scientific organization."

"This statement is true today. In addition, no careful study has ever been made, from a legal standpoint, of the exact limitations of the federal government along public health lines. What can the national government do under the constitution for public health? No one is today in a position to answer this question authoritatively. As a result, bills are drafted and measures proposed that would probably, if adopted, be unconstitutional, while such measures as the Harrison Narcotic Law, a law intended solely for the improvement of public health conditions in a broader sense, are passed ostensibly as revenue measures and are later by amendment converted into revenue producing measures with serious injustice and inconvenience to law-abiding physicians. If Congress has the power to regulate the sale of habit-forming drugs for the public good, then it is not necessary for Congress to pass such measures under the guise of revenue laws which after their passage are distorted and misconstrued by federal officials into unfair and inequitable revenue producing measures. This country will never have a federal department of public health such as has been advocated rather vaguely for fifty years past until the public health functions and powers of the federal government under the constitution have been definitely determined. Two questions must be answered: First, what can the federal government do for public health; and second, what is the federal government now doing for public health. These questions are not at present being considered by any other organization, yet their solution is fundamental to the development of public health in this country. They are problems to which the American Medical Association can fittingly and properly direct its attention. Having secured some authoritative information on these two questions, we will then be able to put the influence of the American Medical Association behind an intelligent movement for a national health organization."

Immediately preceding the Atlantic City session, the Secretary was asked to meet with the Executive Committee of the Association of State Health Officers for the purpose of discussing the reorganization of federal public health work. Later at a joint meeting of the Council and the Executive Committee of the State Health Officers an agreement was made to cooperate in endeavoring to secure a reorganization of federal public health agencies. A joint committee, consisting of the Chairman, the Secretary and Dr. W. S. Rankin from the Council, and Dr. S. J. Crumbine, Secretary of the State Board of Health of Kansas, Dr. C. St. Clair Drake, Director of Public Health in Illinois, and Dr. Allen W. Freeman, Commissioner of Health in Ohio, representing the Association of State Health Officers, was appointed to coordinate the work of the two bodies. After considerable correspondence, a conference was held at the Association headquarters in Chicago, July 28-30, 1919, at which were present the members of the Joint Committee, other members of the Executive Committee of the Association of State Health Officers and advisers on legal and technical questions.

After three days spent in discussing the details of the proposed reorganization and the essential provisions of a bill for this purpose, it was recognized that it was not possible to draft a satisfactory bill for the reorganization of the federal public health work until more information was available regarding the present public health activities of the federal government, what work was being done in the different departments, what appropriations were being made, how much was being spent, what was being accomplished, etc. It was realized that it would be impossible to draft a workable bill without authoritative and official information on these points. The possibility of the Council undertaking a survey of federal public health work was then discussed. Following the adjournment of the conference, this discussion was carried on by correspondence. Continued discussion of it led to the realization of the fact that any such survey carried on by private or unofficial agencies would neither be constructive nor authoritative and that such a study could be made only by a commission created by Act of Congress, authorized and empowered to summon before it the heads of the various bureaus and departments of the federal government, to call for official reports, estimates, records of expenditures, etc., and to carry on a systematic, official survey of the entire health work being done by the federal government, what reorganization and rearrangement was possible and advisable and how this could best be brought about. The Secretary and Dr. C. St. Clair Drake were appointed a Subcommittee to prepare a measure for accomplishing this purpose. Careful study of the situation in Washington, together with an inquiry into the legal and parliamentary questions involved, showed that the best form of securing the end sought was by means of a joint concurrent resolution. Such a resolution was accordingly drafted and introduced into the Senate by Hon. Joseph E. France of Maryland, as Senate Joint Concurrent Resolution 14, and into the House by Hon. E. E. Denison of Illinois as House Joint Concurrent Resolution 33. The resolution provides for a joint committee to consist of three members of the Senate and three members of the House "to make a survey of and report on those activities of the several departments, divisions, bureaus, offices and agencies of the Government of the United States which relate to the protection and promotion of the public health, sanitation, care of the sick and injured and the collection and dissemination of information relating thereto." The Committee is directed to report to Congress

1. The statutory powers and duties conferred by the Congress on any department, division, bureau, office or agency of the United States Government to carry on any work pertaining to the conservation and improvement of the public health, together with any rules and regulations authorized or promulgated thereunder;

2. The organization now existing in the Federal Government for the purpose of carrying out these powers and duties, together with the personnel of, appropriations for, and expenditures by each department, division, bureau, office, and agency during the fiscal year ended June 30, 1919;

3. The coordination now existing between said departments, divisions, bureaus, offices, and agencies, together with any conflict, overlapping, or duplication of powers, duties, functions, organization, and activities;

4. The cooperation and coordination now existing between the Government of the United States and the government of the several States or extragovernmental agencies for the conservation or improvement of the public health;

5. Such further information as such committee may deem proper;

6. Such recommendations as such committee may deem advisable to offer for the improvement of the public health work of the United States Government.

This resolution, which is short and easily understood, provides for the first time for a systematic study of the public health activities of the federal government as a basis for reorganization. The resolution passed the Senate December 20. It was, at the time this report was written, still in the

Committee on Rules in the House, although there is a good prospect of its being adopted by the House at an early date.

At the New Orleans session of the American Public Health Association in October, 1919, one afternoon session was devoted to the discussion of this question, following which the American Public Health Association adopted a resolution unanimously endorsing the action of the joint committee, urging the passage of the resolution by Congress and authorizing the appointment of a committee to represent the American Public Health Association and to cooperate with the joint committee in securing the passage of this resolution. The committee appointed by the President of the American Public Health Association consisted of Dr. Haven Emerson, New York City, Dr. Charles V. Chapin, Providence, Rhode Island, and Mr. Lee K. Frankel of New York.

The formulation of this resolution providing for a congressional survey of federal public health work and the submission of recommendations for the reorganization, coordination and improvement of federal public health activities, constitutes for the first time in the history of this movement a definite, sound and practical program. In the furtherance of this program, the Council has enlisted the cooperation of the American Public Health Association and the Association of State Health Officers. The joint committee which has been created forms an effective means whereby the combined influence of the three organizations represented can be utilized for constructive public health work. The Council feels that for the first time in the history of the Association we are on the right track. It is hoped that the concurrent resolution may pass the House during the present session and the committee may be appointed to carry on its survey during the summer recess of Congress so as to report early in December. If this is not possible, then there are gratifying prospects of the passage of this resolution as soon as the new Congress convenes under a new administration.

MEDICO-LEGAL WORK

In its report for 1919, the Council made the following statement regarding its previous work and plans on medicolegal lines:

"Another task taken up by the Council was a study of the legal relations and responsibilities of physicians and the legal aspects of public health. This field, for obvious reasons, has never been carefully studied either by physicians or lawyers. It offers no prospect of financial reward to lawyers and it is only of interest to physicians so far as their personal interests are involved in some specific case. The Secretary has for many years collected a large amount of material on this subject. One volume of a proposed four-volume set was issued in 1915, namely, "Digest of Supreme Court Decisions on Medical Practice Acts," in which were indexed 752 court decisions on this subject, 396 of which were abstracted. Work was begun and nearly completed on the second volume, "A Digest on the Medicolegal Relations of Physicians," for which approximately 1,800 supreme court decisions were collected and abstracted. This work can probably be completed and prepared for publication in a few months. In the field of malpractice, there are probably 1,500 cases on record which have gone to courts of last resort for opinions, while on the fourth subject, "The Powers and Duties of State Boards of Health," there are approximately 800 decisions on record. This work should be completed and published, as it comprises material that is not available in any other form nor through any other agency."

During the past year the second volume of the medicolegal series on "Medicolegal Relations of Physicians" has been completed and is now being prepared for publication. This digest contains 3,000 Supreme Court decisions on all the personal, legal relations of physicians except malpractice and will be of great value to the profession in affording authoritative information on many legal questions of vital importance to physicians. Plans are now being made for the compilation of the third volume on "Powers and Duties of Health Officers" which the growing work of municipal, county and state health departments has rendered imperative.

VITAL STATISTICS LEGISLATION

In its report for 1919, the Council summarized the history of vital statistic legislation in this country showing that, in 1906, at the time that the Committee on Medical Legislation, the forerunner of the Council on Health and Public Instruction, took up this work in cooperation with the Division of Vital Statistics of the Bureau of the Census, there were only ten states in the Union that had any effective laws for the registration of deaths and only eight in which there was any birth registration, and that through the formulation of the model bill on vital statistics and the cooperation of the various organizations interested, the model bill had been adopted in the past fourteen years in all of the states except seven, viz., Alabama, Arizona, Delaware, Iowa, Nevada, South Dakota and West Virginia. During the past year, Alabama and Delaware have adopted the model law, leaving now only five states which are as yet without satisfactory legislation on this subject. These are Arizona and Nevada, in which no satisfactory system of registration has ever existed; Iowa and West Virginia, in which the old obsolete system of registration through county clerks still persists; and South Dakota, in which the Secretary of the State Historical Society is the Registrar of Vital Statistics which are collected and recorded as historical rather than public health data. In Arizona and Nevada, the model law should be adopted at the next session of the legislature. In the other three states such amendments to the existing law should be adopted as will render these states eligible to admission to the Registration Area of the United States Census. This work, which is absolutely essential for any modern public health work, should be completed at the earliest possible moment so that the Registration Area for Births and Deaths in this country will include the entire country.

The House of Delegates has repeatedly endorsed the model law and has repeatedly urged its adoption on the various state associations. This support has been of the greatest assistance in securing the passage of these laws in the different states. In order that this work may be completed, the Council requests the House of Delegates to reaffirm its endorsement of the model law and to urge the state medical associations in Arizona, Iowa, Nevada, South Dakota and West Virginia to take the lead in educating public opinion in these states and to endeavor to secure at the next session of their legislature the adoption of such measures as will bring their states into the Registration Area in harmony with the rest of the country.

COMMITTEE ON PROTECTION OF SCIENTIFIC RESEARCH

The Committee on Protection of Scientific Research which has done such excellent work in the past in educating the public and in preventing the passage of legislation restricting scientific investigation has during the past year done one of the best pieces of work in its record. Senate Bill 1258, introduced by Senator Myer of Montana, while apparently only intended to forbid the use of dogs for experimental purposes in the District of Columbia, was in reality an opening wedge for general restrictive legislation. The bill was referred to the Judiciary Committee of the Senate and by this Committee was referred to a subcommittee consisting of Senator Norris of Nebraska, Chairman, Senator Colt of Rhode Island and Senator Ashurst of Arizona. Hearings covering several days were held in Washington the first week of November, 1919. The usual lobby of antivivisectionists, officers of antivivisection societies and others was present to urge the passage of the bill. The scientific side of the case was presented by an imposing array of distinguished scientific men under the leadership of Dr. Walter B. Cannon of Harvard Medical School. It is doubtful if any discussion of this question has ever been more brilliantly or convincingly conducted. The full report of the hearing published by the committee forms an interesting collection of scientific data as well as an exposition of the misstatements and fallacious arguments of the antivivisectionists. The bill has never been reported out of committee.

Soon after the organization of the original Committee on Defense of Scientific Research, a set of rules for the care of

animals in scientific laboratories was formulated, printed and copies distributed to each medical college and scientific laboratory in the country with the request that they be posted and enforced. This voluntary action on the part of the medical profession for the regulation of any possible abuses in animal experimentation has proved one of the strongest arguments against the adoption of special legislation for this purpose. Although these rules are still being enforced, the length of time that has elapsed since their distribution made it advisable in the opinion of the Committee to print a new edition of the rules and send them out to all scientific laboratories. Copies of these rules with a circular letter have been sent to each of the eighty-five medical colleges and eleven additional laboratories. Requests for additional copies have been received from many of the laboratories and the rules have been posted and are being enforced now in practically all of the scientific laboratories throughout the country.

In addition to the series of twenty-eight pamphlets on Protection of Scientific Research prepared by the Committee and issued by the Council which has now become a standard series on this subject, two other pamphlets are now in course of preparation, one on the value of animal experimentation in the study of nutrition by Professor McCollum of Johns Hopkins University, and the other by Doctor Cannon, the Chairman of the Committee, summarizing the entire series and presenting in a single, concise pamphlet the entire case for scientific research, with special reference to the question as to why the dog is essential to scientific investigation.

COMMITTEE ON CONSERVATION OF VISION

At the annual meeting of the Council held on October 4, 1919, the following Committee on Conservation of Vision was appointed: Dr. Cassius D. Wescott, Chairman, Chicago; Dr. George S. Derby, Boston; Dr. George Edmund de Schweinitz, Philadelphia; and Dr. John E. Weeks, New York City. In addition to the twenty pamphlets now on hand forming the popular series on Conservation of Vision, two others are now under consideration, one on crossed eyes and one on cataract. The Chairman of the Committee and the Secretary of the Council have held several conferences with a committee from the American Optical Association with a view to the inauguration of a campaign for the education of the public on conservation of vision and the detection and correction of errors of vision, especially among schoolchildren and industrial employees. This plan which is developing rapidly will, if consummated, be financed by the American Optical Association and directed by a committee on which the Council and its Subcommittee will be represented.

COMMITTEE ON COOPERATION WITH THE NATIONAL EDUCATION ASSOCIATION

This Committee which is at work on health problems in education was reorganized at the October meeting of the Council by the appointment of the following Committee: Dr. John M. Dodson, Chairman, Chicago; Dr. R. W. Corwin, Pueblo; Dr. George W. Goler, Rochester, N. Y.; Dr. Edward Jackson, Denver; and Dr. Henry L. K. Shaw, Albany, New York. Dr. Dodson, Dr. Corwin and Dr. Goler attended the annual meeting of the National Education Association in Cleveland on February 24. A fourth pamphlet in the series prepared by this Committee on the results of health conservation work in the rural schools is now in preparation.

COMMITTEE ON SOCIAL INSURANCE

This Committee, appointed by the Council in 1915 to carry on a study of social insurance in its relation to the medical profession, presented reports to the House of Delegates at the annual sessions of 1916, 1917 and 1919. No report was presented in 1918 owing to the fact that Doctor Lambert, the Chairman of the Committee, was in service in France. The House of Delegates each year has approved of the report of the Committee, and has directed it to continue its work. The House of Delegates has not as yet seen fit to commit the Association to any positive position on this question, evi-

dently feeling that the time had not yet come for the Association going on record either for or against social insurance. Members of the House of Delegates, of course, understand that the House of Delegates is the only body under the Constitution and By-Laws of the Association that has any power or authority to adopt any policy or commit the Association to any opinion on this or on any other question. Its determination lies entirely outside the jurisdiction of the Council. Evidently this fact is not clearly understood by many of our members, inasmuch as in the last few months statements have appeared in several of our state journals either in the editorial or correspondence columns criticizing the Council for failure to take a positive position against social insurance. Such criticism, of course, is entirely unwarranted as it is not the function of the Council to formulate the policies of the Association.

The failure of the Davenport bill to pass the New York legislature leaves no state in which this question is at present up for discussion in any concrete form, while the growing opposition of physicians and the increasing attention given to it in professional circles will probably prevent the passage of social insurance bills in any state without the medical profession being thoroughly informed and prepared to participate in the discussion of them. The objects which the Council had in view in creating this Committee, viz., to arouse the medical profession to a discussion of this subject and to prevent the premature adoption of any such measures in this country as in England without the full knowledge of the medical profession, have evidently been accomplished.

MIDWINTER CONFERENCE

The regular Midwinter Conference on Public Health and Legislation was held at the Auditorium Hotel in Chicago on Thursday, March 4. Owing to the war, this was the first conference which the Council has held since 1917. In spite of this lapse of three years and of the fact that many state and municipal health officers were unable to attend on account of serious epidemics, the attendance was one of the largest and most gratifying that has been present at any of the conferences of the Council. Following the policy of making this Midwinter Conference a rallying point for other organizations, committees, councils, conferences, etc., an effort was made to concentrate as many meetings as possible in the week of the session. The Executive Committee of the State Health Officers, the Joint Committee of the Council, the State Health Officers Association and the American Public Health Association, the Executive Committees of the American Public Health Association and the National Tuberculosis Association and the National Association of Colleges and University Health Officers were all held in connection with the Conference. Plans are now under consideration for a more extensive Conference next year and for the centering of the greater number of our public health meetings and conferences at this time.

SPECIAL COMMITTEES

The Council desires to bring to the attention of the House of Delegates a growing tendency to relapse into the conditions which existed before the creation of the Council in regard to the appointment of special and independent committees. Previous to the organization of the Council, there had developed during a number of years many independent and overlapping committees, each of which was endeavoring to functionate separately and independently and each of which was asking for appropriations to carry on its work. In order to concentrate all of the public health and public relation functions of the Association under a permanent and responsible Council, the House of Delegates in 1910 created the Council on Health and Public Instruction which took over all of these conflicting and independent committees. In the last few years there have been created several independent and uncoordinated committees for special purposes, usually in response to a motion of resolution introduced by some member of the House often without careful consideration of its relation to the existing executive machinery of the Association. Special committees appointed in the

midst of the annual session are often hastily selected and without due consideration to the various factors deserving of recognition. Much better results are secured by the creation of such special committees as may be needed as subcommittees of one of the existing permanent boards or councils, selecting men carefully after due consideration to the needs of the situation. The Council, therefore, recommends that the House of Delegates, in taking action on subjects lying within the field of the Council, instead of creating special and independent committees, instruct the Council to appoint such committees and to inaugurate and carry on their work as a part of the Council activities.

INCREASED TAXATION UNDER THE HARRISON LAW

In its report for 1919, the Council called attention to the increased registration tax for physicians under the Harrison law which had been increased from one to three dollars. The Council pointed out that this law was enacted by Congress to carry out our international obligations in compliance with the recommendations of the Shanghai Commission on the Control of Opium Traffic; that it was extremely doubtful whether Congress had any authority under the Constitution to regulate the importation and sale of a drug so long as the object of the regulation was the improvement of the public health or moral status of the people; and that in order to give Congress jurisdiction on this subject, the Harrison law, like the Esch phosphorus bill, had been put in the form of a revenue measure. The American Medical Association and its Journal cooperated heartily and cheerfully in the enactment of this measure, in the hope that it would be of material value in restricting the use of narcotic drugs to legitimate purposes. The medical profession of the country also accepted the imposition of a tax and the inconvenience of registration as its contribution to the operation of the law and as necessary accompaniments of any practical plan for the control of illicit traffic in habit forming drugs. The object of the law is not and never has been the production of revenue. The revenue feature is incidental and secondary. Yet in the revenue bill for 1918 the license tax for physicians under the Harrison law was increased from one to three dollars. Estimating the number of physicians in the United States at 150,000, this increase of two dollars a year forms an unwarranted and inequitable tax on physicians of \$300,000 a year. A license law is no more effective with a three dollar license fee than with a one dollar fee. The only possible justification for the Harrison law is the public good. The expense of the operation of the law, therefore, should be borne by the public and not by a special tax levied on one particular class. While the increase in the tax on physicians might have been justified in 1918 as a war measure, now that the war is over there is no possible justification for its continuance. The Council, therefore, recommends that the House of Delegates record its emphatic disapproval of this exploitation of physicians and that it demand the reduction of the registration fee for physicians to a nominal amount for so long as the law remains in force.

REGULATION OF HABIT FORMING DRUGS

The Harrison law has now been in operation a sufficient length of time to afford a fair opportunity for determining its effectiveness. It must be admitted that it has failed of the purpose for which it was enacted, viz., the restriction of the use of habit forming drugs to legitimate purposes. While definite figures are lacking, it is estimated that there is at present imported each year into this country between four and five times as much opium as is needed for medical purposes. Reports indicate that efforts to enforce the law in the face of this oversupply of drugs have resulted in a marked increase in the illicit distribution of opium, morphin, heroin, cocain and other inhibited drugs, while the extortion of unfortunate victims of drug habits has been made possible by the illegal methods under which the traffic is necessarily carried on. The enormous profits of illegal traffic in drugs has led to systematic efforts to increase the number of prospective customers while the opportunities for profits due to the dishonest enforcement of the law in differ-

ent localities has led to blackmail and official corruption. The present situation is exactly the same that would have resulted if a federal law had been passed forbidding the use of alcoholic liquors but leaving their manufacture and distribution unrestricted. The attempt to regulate the use of habit forming drugs and to restrict their use to legitimate purposes by a license law has evidently failed. Nothing but continued failure and scandal can result so long as it is possible to produce and bring into this country each year many times the amount of these drugs needed for legitimate purposes. The only effective method of control is by the government, through the U. S. Public Health Service, being given complete control of the importation and distribution of habit forming drugs, the forbidding of their manufacture or importation by any private individual or firm, the ascertaining of the approximate amount needed each year for legitimate purposes, the importation of this amount under government control and its distribution to properly qualified and registered persons through the Public Health Service with the requirement of strict accountability for all drugs issued. The Council recommends that it be instructed to inaugurate an investigation into (1) the amount of narcotic drugs required for each year for legitimate purposes; (2) the amount of narcotic drugs now actually imported into the country; (3) the devising of effective methods by which these drugs under proper government supervision may be restricted to legitimate uses.

The tabulation of the educational material printed and distributed by the Council, together with the work done by the headquarters office, is submitted herewith:

Report of Council on Medical Education

Dr. A. D. Bevan, Illinois, Chairman, presented the report of the Council on Medical Education, which was referred to the Reference Committee on Reports of Officers.

The report follows:

To the Members of the House of Delegates of the American Medical Association:

The functions of the Council on Medical Education are:

1. To make an annual report to the House of Delegates on the existing conditions of medical education in the United States.
2. To make suggestions as to the means and methods by which the American Medical Association may best influence favorably medical education.
3. To act as the agent of

TABLE 1.—ENROLMENTS OF MEDICAL STUDENTS FOR SIX YEARS, SHOWING VARIATION IN NUMBERS BY CLASSES

College Session	Freshmen	Sophomores	Juniors	Seniors	Totals
1914-1915	3,373	3,919	3,675	3,864	14,891
1915-1916	3,582	3,094	3,559	3,727	14,022
1916-1917	4,107	3,117	2,866	3,674	13,764
1917-1918	4,283	3,521	2,893	2,933	13,630
1918-1919	3,104	3,587	3,272	3,089	13,052
1919-1920*	4,069	2,760	3,306	3,267	13,564

* Estimate.

The single line drawn through the table undercores the figures which show the lowest ebb in the enrolment in the respective classes following the adoption of higher entrance requirements. The smaller number of freshmen in 1918-19 was due to enlistments in the World War. While the figures for 1919-20 are estimated they are fairly accurate since reports from all but a few colleges were obtained.

TABLE 2.—CAPACITY OF MEDICAL SCHOOLS UNDER LIMITED ENROLMENTS

the American Medical Association in its efforts to elevate the standard of medical education. Having these functions in mind, the Council desires to submit the following report:

I. PRESENT STATUS OF MEDICAL EDUCATION

In 1906, the United States had 162 medical schools, or over half the world's supply. The number has been reduced, largely by the merging of from 2 to 5 medical schools in each of various cities, until now there are 86. Although the number is reduced, the character has been greatly improved. Of the 86 now existing, 77 are regular or non-sectarian; 5 are homeopathic; 1 is eclectic and 3 are nondescript affairs, 2 of which are semi-osteopathic and the third is not recognized in its own state (Missouri).

Since 1906 the proportion of medical schools requiring college work for admission increased from only 4, or 3 per cent. of the 160 medical colleges, to 79 or 92 per cent. of the 86 colleges now existing. The changes in this respect are shown in Chart 1.

Through the reduction in the number of medical schools and the adoption of higher entrance requirements, a material

reduction in the number of medical students was expected. The total has been reduced from 28,142 in 1904 to 13,052 in 1919 but the quality of the students has been very largely improved.

During the present college session the enrolment is approximately 13,554 students, or about 500 more than were enrolled a year ago. As shown by Table 1, the lowest ebb in enrolments following the adoption of higher requirements has been passed and a rapid return to larger enrolments is to be expected.

EFFECT OF PRELIMINARY REQUIREMENTS ON STUDENT ENROLMENT

Early in the campaign for higher requirements of preliminary education some feared that medical schools would be unable to secure students. A reduced enrolment in the first session naturally followed the adoption of the higher requirements but in subsequent sessions, in all the better medical schools, enrolments have returned to normal proportions. The present enrolments in freshman classes in most schools greatly exceed those of the previous years. Furthermore, the enrolments in pre-medical classes show that still larger numbers will begin the study of medicine in the next two years. It is important, therefore, that only those be admitted who are well qualified to study medicine. Scholarships are being rapidly established so that few students need be barred because they are lacking in money.

The present enrolment in all medical schools based on returns from the majority of institutions is estimated at 13,554, an increase of 502 over the total enrolment in 1919. It is evident, therefore, that following the enforcement of higher standards for admission, the low mark in the number of matriculations has been passed, and that higher enrolments in subsequent years may be expected.

LIMITATION OF ENROLMENTS

The limitation of enrolments by some medical schools and the excessive numbers of premedical students have caused some alarm lest medical schools may not have room for all the well qualified students who apply. An investigation (see Table 2) shows that the 16 Class A medical schools which have limited their enrolments can care for 4,559 students. Thirty-nine medical schools report that their maximum capacity with efficiency of teaching would enable them to care for a total of 9,061 students. An estimate based on the inspection of 13 Class A medical schools from which no reports were received shows they can enroll and properly train altogether about 1,810 students. The 68 medical schools in Class A, therefore, could enroll without overcrowding 15,430 medical students or about 1,500 more than are at present enrolled (13,554 est.) in the 85 medical schools of the United States. By securing more teachers; by the enlargement of laboratories, and by the completion of college buildings already planned or in course of construction, the numbers of medical students who can be satisfactorily taught could be further increased to 17,000 or 18,000 students.

The existing medical schools, therefore, are more than adequate to meet present needs, and in future as the numbers of students may increase, ample provision can be made for them.

It is the duty of the better medical schools to enlarge their facilities so as to care for as many students as possible, since otherwise many well qualified students will be forced into poorer schools.

THE AMERICAN STANDARD OF MEDICAL EDUCATION

The standard of medical education as it has developed in this country, and which may be called the American standard consists of:

- (a) Two years of premedical college work.
- (b) Four years in an acceptable medical school, and
- (c) A year's internship in an approved hospital.

Of the 86 colleges, as shown in Chart 1, 78 now require for admission 2 years of college work in addition to a four-year high school education. The admission requirements to

medical schools in the United States are now on a par with those in other leading countries.

The Council's "Ideal Standard," adopted in 1905, urged medical schools to require for admission a year of college work, including courses in physics, chemistry and biology, this work to be obtained either in a college of arts and sciences or in the medical school. A special committee of the Council in 1907, however, found that most colleges of arts and sciences did not favor disarranging their schedules so to give in a single year three sciences which included laboratory work. Medical schools which were departments of universities proceeded rapidly to require two years of college work for admission. A few medical schools established premedical courses, but in no instance was the work given in a satisfactory

manner. It was soon evident that the Council's one-year requirement should be merely a stepping stone to the two-year standard. Since Jan. 1, 1918, therefore, in accordance with instructions from the House of Delegates in June, 1916, the requirement of two years of college work for admission has been an essential for the Class A rating. Only one medical school is now offering a premedical science course. All others are requiring that the work be taken in colleges of arts and sciences.

The advantages in requiring that the premedical work be taken in approved colleges of arts and sciences are:

(1) The physics, chemistry and biology are taught without reference to their special bearing on medicine. It is not known today what particular facts obtained in the study of these sciences will be most useful in the medical research of tomorrow.

(2) The quality of the premedical work is assured since it is obtained in reputable colleges of arts and sciences in the course leading to the degree of Bachelor of Science. This provides also a satisfactory standard for measuring the value of irregular or so-called "equivalent" courses.

CHART 1.—MEDICAL SCHOOLS AND ENTRANCE REQUIREMENTS

The heavy line at the top shows the total numbers of medical schools existing in the various years. The horizontal shading (indefinite) shows those requiring for admission a four-year high school education; the vertical shading those requiring one year of college work and the heavy shading those requiring two years of college work.

Figures show (a) those requiring for admission a high school education or less; (b) those requiring one year of college work; (c) those requiring two or more years of college work.

(3) The student is left free to make a final choice of his life work until he is best qualified to do so. He may have medicine in mind when he enters the university but he enters the classes working for the Science degree. He has a chance to compare notes with those studying for other callings and may find that he is better fitted for some other occupation or profession than medicine. If so, he can make the change without any loss of time (see Chart 2) since his premedical courses are equally acceptable toward other callings. Had he enrolled immediately in a premedical course of a medical school and then desired to change to some other profession it might be at the loss of one or more years spent in premedical work. This freedom of choice is of great importance since reports show that from 10 to 30 per cent. of "premedical" students change to some other calling before their two-year course is completed.

(4) Students now enter medical schools with the benefit of two years under the college influence and atmosphere, the contact with students in other departments, the social life, and the athletics, which are bound to affect their entire lives.

(5) The arrangement is a safeguard against medical cults. A student who, in a reputable college, has studied genuine science in his courses in physics, chemistry, and biology will seldom be misled by the fallacious claims advanced by unscientific cults.

The one disadvantage of the arrangement is the lack of uniformity in the courses in physics, chemistry and biology given in different colleges or universities. Efforts are now being made to correct this defect.

THE HOSPITAL INTERN YEAR

This part of the Council's educational standard, adopted in 1905, is largely taking care of itself. For many years a large majority of medical graduates have voluntarily secured internships in medical hospitals and the proportion has rapidly increased since

ten state licensing boards have required internship as an essential qualification for the license. These states are Pennsylvania, New Jersey, Alaska, Rhode Island, North Dakota, Washington, Illinois, Michigan, Iowa and Texas.

Eleven medical colleges have adopted the requirement of a fifth year to be spent by the intern in an approved hospital before the M.D. degree will be granted. Many more hos-

from the interns also information in regard to the character of the hospital is obtained. A somewhat similar scheme is reported as working out fairly well at the University of Minnesota Medical School also. The colleges which have adopted the intern year as a requirement for the M.D. degree and the years when the requirement became, or becomes, effective are given in the accompanying table.

SUPPLY OF HOSPITAL INTERNS

There is a real demand for medical graduates to serve as interns in hospitals, but this demand could not be met even if the number of medical colleges and the number of graduates annually should be doubled or trebled. The number of hospitals seeking interns has been tremendously increased and new hospitals are rapidly being erected. Last year 1,126 hospitals, with a total of 270,000 beds, were using or seeking interns. Counting that one intern is needed for every thirty beds, these hospitals would require 9,000 interns each year—more than three times the number of medical graduates in 1919! No such number of graduates is necessary to meet the normal demand for physicians. The intern problem requires some other remedy:

(a) The internship might be extended to two years by which the annual output of graduates would supply twice as many hospitals.

(b) The hospitals might pay salaries to recent graduates inducing them to remain for several years as resident physicians or surgeons.

(c) Hospital assistants or nurses might be trained to do much of the work now devolving on the intern—as suggested by Dr. Goldwater.

(d) The situation is relieved in some hospitals by the employment of stenographers who, at the time the patients are examined, take down histories from dictation by the members of the attending staff.

Meanwhile, the number of hospitals is now so large that only those will be able to secure interns which are willing to furnish a valuable clinical training.

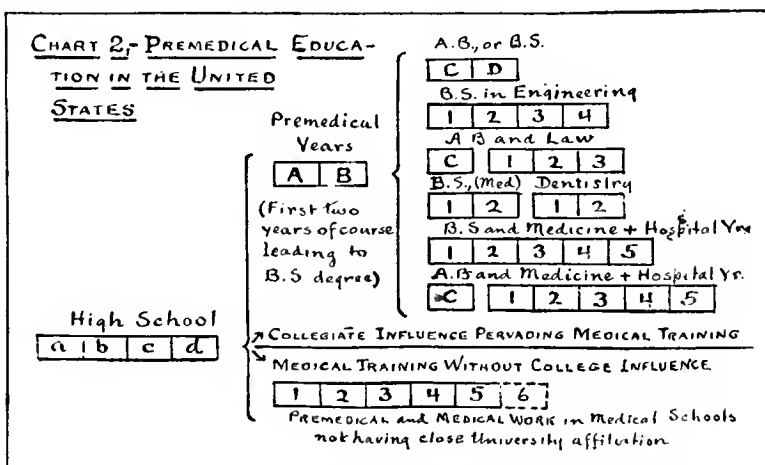

NO SCARCITY OF PHYSICIANS; NEED BETTER DISTRIBUTION

A tabulation prepared in August, 1919, shows that the United States has one physician to every 720 people as compared to one to 1,500 in Great Britain. Investigation shows that, with a few exceptions, the demands made for physicians come from the sparsely settled districts in which it would be difficult for a physician to make a living.

The main difficulty is the imperfect distribution rather than a shortage of physicians. Meanwhile, the medical care for rural districts is being gradually improved through better roads, the use of automobiles, interurban railways, telephones and other like improvements. These are enabling the patients in rural districts to obtain more readily the services of physicians in nearby cities.

The Council on Medical Education is now making another survey of all medical schools, the purpose being to ascertain the present problems in medical education. This survey is revealing many changes since 1904; new buildings, more and better equipped laboratories, many more full-time teachers, greatly increased financial resources, closer relations with hospitals and dispensaries, more abundant clinical facilities and greatly improved methods of clinical teaching are everywhere in evidence. The very radical improvements in certain

CHART 2.—PREMEDICAL EDUCATION IN THE UNITED STATES

This chart shows (a) that the student is under the influence of college life and atmosphere during his two premedical college years; (b) that he is not required to make a final decision in regard to his life work until he has finished all premedical work, and (c) that at any time he can change to some other calling without difficulty.

pitals are now seeking interns than can ever be supplied by medical schools. This gives the college the opportunity to select for its students those hospitals which are considered in best position to furnish adequate intern training. Under the method devised by Rush Medical College of Chicago, the faculty arranges with some member of the attending staff of each approved hospital to report at regular intervals regarding the work done by the intern. Through reports

particulars cause the present conditions to stand out in strong contrast to those found in the Council's survey in 1906.

EXIT THE UNEQUIPPED MEDICAL COLLEGE

About 40 of the 162 medical schools existing in 1906 were without laboratories and without clinical material, yet in 1907 each of these institutions turned out from 12 to 105 graduates. Now most of the medical schools have from five to fifteen well equipped laboratories, and there is not one which does not have at least three laboratories. As to clinical material most medical colleges now actually own or control a teaching hospital, while there is not one which does not have relationship with a hospital in which at least amphitheater clinics can be held.

INDEPENDENT MEDICAL SCHOOLS DISAPPEARING

Again private medical schools—those not having university connection—have largely disappeared. Now of the 85 medical schools, 66 are actually medical departments of universities and in 52 of these the universities have assumed full control not only of the entrance qualifications of the students admitted but also of the finances and the methods of teaching, so that the academic spirit of the university now pervades the medical school also. Of the 68 Class A medical schools, 60 are departments of universities. The influence of university life has been largely increased since now the students have obtained two years of premedical preparation in the liberal arts college.

Of the 86 medical colleges now existing 70 are in Class A, 8 are in Class B and 8 in Class C. Of the 70 in Class A, 59 give the complete four-year course, while 11 offer only the first two years.

When the present survey of medical schools is completed, the Council is planning a revision of its classification. There is, at present, a wide variation between the highest and the lowest of the medical schools now rated in Class A. It is contemplated, therefore, that a subdivision of the Class A group be made, placing the 25 or 30 medical schools which come up to a definite standard in a Class A+, and leaving in A those which are doing sufficiently good work that they can be recommended to all state licensing boards. Certain medical schools which are found seriously deficient will have their rating changed to Class B. It is expected that this subdivision of the present Class A group will lead those rated in A to bring about further improvements.

II. MEASURES OF IMPORTANCE IN MEDICAL EDUCATION

The second function of the Council was to suggest the means and methods by which the American Medical Association can best influence favorably medical education. In this connection we submit the following:

IMPROVING HOSPITAL SERVICE

The Council has given a great deal of careful study to the conditions underlying hospital service which is clearly one of the most important problems now confronting the medical profession, and is convinced that the American Medical Association with its constituent state societies is particularly well equipped to carry on this work. In this connection, the following statement will show the progress of the work in connection with hospitals conducted by the American Medical Association and its Council on Medical Education.

HOSPITAL WORK OF THE AMERICAN MEDICAL ASSOCIATION

Since 1903, the American Medical Association has conducted a clearing house of information relating to all matters in which physicians are interested. This has included information relating to hospitals. From a small beginning the information has rapidly increased in quantity as have also the sources and methods of obtaining information. At first, the information consisted of data obtained through correspondence with physicians, references to articles relating to hospitals and hospital problems published in *THE JOURNAL*, references to books dealing with these problems, etc. As hospitals increased in numbers and as the demand for information increased, the means for obtaining data were also expanded so that, at the present time, the Association has under the Council on Medical Education, a definite Bureau

on Hospitals, which in 1918 had a man who devoted part of his time to the work and for the last year another man has been engaged on full time. This work is intimately tied up with that relative to the many other lines of work carried on at the headquarters of the American Medical Association and especially with medical education, medical licensure, the biographical index and the medical directory. The bureau is aided by committees in the various states, representing the state medical societies, which, in turn, work in harmony with the county societies of their states.

This work of collecting information relating to hospitals and the furnishing of such information to those having need of it, therefore, has been a continuous but a constantly increasing work since 1903. There have been intervals, however, when special and more extensive efforts have been made to secure information in connection with hospitals.

In 1905, a closer relationship between the American Medical Association and hospitals was established when the Council on Medical Education urged that an internship be required as a part of the regular medical course. In 1905, also, the work with hospitals received an additional stimulus through the more detailed information which was obtained from all hospitals as a basis for the lists published in the American Medical Directory.

In 1912 a careful reinvestigation of all hospitals was made for the purpose of ascertaining which were in a position to furnish acceptable internships.¹ Such information as had been collected by the Council through reports from the hospitals, special questionnaires, etc., was submitted to the various state committees for verification. These committees did excellent work, and in several states inspections were made of most or all of the hospitals.

The following schedule was adopted in order that a uniform standard of measurement might be provided for the use of all committees. The outline follows:

1. Buildings and grounds; light; heat; ventilation; repairs; cleanliness, etc.
2. General supervision; superintendence, etc.
3. Trustees; ownership and general conduct; whether conducted in the interests of the community and scientific medicine, or solely for the profit of the attending staff.
4. Medical staff; its organization, character, etc.
5. Intern service: existence of; proportion of, to patients.
6. Nursing; training school for nurses; orderlies, etc.
7. Laboratory; roentgen ray, clinical, laboratory facilities, etc.
8. Records; histories; library, etc.
9. Out-patient department; emergency service; necropsies, etc.
10. Educational functions; teaching; research; influence on local profession, etc.

This general survey of 1912-1914, covered 2,224 hospitals having twenty-five or more beds and reports were received from 2,085, or 98.2 per cent. The reports provided more reliable and up-to-date information regarding all hospitals and enabled the Council in 1914 to publish in tabular form information relating to 852 hospitals which provided internships for 3,006 interns annually. A small, first edition of this tabulation was printed in February, 1914; it was submitted to the various state committees for revision and, after numerous corrections, was published in October, 1914. About 5,000 copies of this pamphlet were printed and circulated. The medical schools were provided with a sufficient number of copies so that each senior student could obtain one.

In a later general survey, that of 1915-1916, the committees of twelve states inspected all or most of the hospitals in those states. In Pennsylvania all hospitals were inspected by a committee of the Bureau of Medical Education and Licensure the chairman of which was a member of the State Advisory Committee on Hospitals. In New Jersey, also, all hospitals were inspected by a joint committee of the State Board of Medical Examiners and the state medical society. This committee also was the one appointed to cooperate with the Council on Medical Education. Based on the data thus obtained, a second revision of the list of hospitals providing internships was published in August, 1916. The list contained the names of 687 hospitals which provided 3,340 internships each year—more than could be filled by the number

1. The results of this investigation were presented at the annual conference of the Council on Medical Education in February, 1915, and the report including the personnel of the various state committees was published in the American Medical Association Bulletin, March 15, 1915, page 316.

of students being graduated annually. The demand for this pamphlet has been constantly increasing.

The records showed that the number of hospitals had been largely increased since the previous inspection and information brought to light a larger number of small, private hospitals, so that, all together, there were approximately 5,000 hospitals having twenty-five or more beds. It was seen that an era of hospital construction had already well begun which likewise called for larger facilities for the collecting and preparation of information relating to hospitals and hospital problems.

Early in 1918 the third general survey of all hospitals was begun. As in previous surveys, an abundance of information collected by the Council was sent to the state advisory committees for their guidance in the work. This information included: (a) Digests of information collected by the Council regarding all hospitals in the state. (b) Lists of all hospitals in the state as published in the latest directory. (c) A collection of selected literature bearing on hospitals and hospital efficiency. (d) A letter of instructions by which state committees would carry on the work in a uniform manner. (e) A tentative schedule of the essentials in a hospital for the satisfactory training of interns. (f) Forms on which additional data might be obtained by the committees as well as blanks on which reports of each committee's work could be prepared and returned to the Council.

Each committee was asked to consider the material sent and to inspect all hospitals as far as possible, or otherwise verify the information relating to each institution and to furnish the Council with an A-B-C rating for all institutions. In this survey, as reported a year ago, it was found there were approximately 6,000 hospitals having twenty-five or more beds, a total capacity of 250,000 beds.

The committees are still at work but reports have already been sent in for 1,298 hospitals of which 1,240 have been graded. Of these, 323 (26 per cent.) are in Class A; 448 (36 per cent.) are in Class B; 321 (26 per cent.) are in Class C, and 148 (12 per cent.) are below Class C. These ratings are being systematically recorded and the supporting data filed. Reports regarding certain disreputable hospitals have been obtained and these are barred from the lists published in the American Medical Directory.

The Association is informing itself thoroughly as to how well each hospital is meeting the needs of its community. At the same time it is giving the hospital the best possible assistance and information.

ATTITUDE OF HOSPITALS

Hospitals, generally, are taking the common sense view, that the survey is a part of a large movement for hospital betterment. They see that hospital standardization is an inevitable process, and that they will soon be expected to measure up to certain standards of equipment, organization and practice. Many of them strive promptly to effect the improvements in organization and in service necessary to secure and retain a Class A rating.

GROWTH OF HOSPITAL SERVICE

The character of our correspondence shows that the hospital information collected is rapidly turning to service. Requests are constantly coming from hospital staff members, superintendents, physicians, interns, nurses, and others for advice and information about hospital architecture, construction, management, staff organization, money raising campaigns, intern problems, nursing and the training of nurses, special hospitals, laboratory work, records, standards, social service, special courses, industrial medicine, etc. The indexing of information under appropriate titles has enabled us to promptly furnish the information requested.

A series of articles presenting hospital plans of special merit have been prepared in collaboration with several architects and are being printed in *THE JOURNAL*.

The "Schedule of Essentials in a Hospital for the Satisfactory Training of Interns" reported last year has been welcomed and several thousand copies have been distributed. In response to an insistent demand from persons responsible for the operation of hospitals, we are preparing a schedule

of essentials for all hospitals which are to be given an acceptable rating whether they desire interns or not.

Another revision of the list of hospitals that furnish acceptable internships, will soon be ready for publication. Like the previous issues, it will be in tabulated form and will include a great deal of detailed and useful data relating to the hospitals, showing those that admit women interns and those that have training schools for nurses.

The rapid growth of hospital service indicates that the work should be continued along the following lines: (a) Push the collection of data regarding hospitals from all possible sources so that the clearing house for such information may become still more serviceable. (b) A further development of the Hospital Service Department in *THE JOURNAL* and the accumulation of a line of hospital literature. (c) Perpetuation of indexes and classifications already completed or begun. (d) Provision for inspection of hospitals where it is considered necessary, and where inspection by other agencies does not furnish satisfactory information. (e) Creation of a permanent hospital committee in each state and the retaining on it of competent and experienced men. (f) Continuation of the relationship with the individual hospital by which we may not only obtain information direct from the hospital but also that the hospital may receive the greatest benefit from such cooperation. (g) A friendly cooperation with other agencies working for the betterment of hospital service.

AGENCIES INTERESTED IN HOSPITAL DEVELOPMENT

The American Medical Association, as the organization representing the medical profession of America, must necessarily continue its splendid clearing house of information on hospital matters the same as it supplies information on other topics in which physicians are interested. With its component state and county medical societies; with its complete biographical index of physicians and with its close relations with medical colleges and state licensing boards, the Association is admirably equipped to carry on efficient investigations with much less expense than is possible by other organizations. At the same time the Association welcomes the work done by other organizations and will lend its hearty cooperation toward the common end.

The American College of Surgeons during the last few years has conducted an investigation of hospitals. Their appeals to the attending staffs, boards of trustees and the public have stimulated an increased interest in hospital standardization. The Catholic Hospital Association also began an energetic campaign for the improvement of the hospitals in that denomination. The rapid growth in both the number and the size of hospitals shows that the field for investigation is not only extremely important from the public point of view but is also large and difficult. There is, therefore, room for all the work that can possibly be done to bring about a continuous and systematic supervision of these institutions which are of such vast importance to the public.

THE AMERICAN CONFERENCE ON HOSPITAL SERVICE

At the annual conference of the Council on Medical Education in March, 1919, following an address by the president of the American Hospital Association, a resolution was adopted which led to the creation of the American Conference on Hospital Service. The first meeting was called by the President of the American Medical Association and held in the Association Building Monday, April 21, 1919. Delegates were present from the American Medical Association, the American Hospital Association, the American College of Surgeons, the Association of American Medical Colleges, the Catholic Hospital Association, the American Nurses' Association, the American Association of Hospital Social Workers, the Federation of State Medical Boards of the United States. A partial organization was effected under the name of the American Hospital Conference and, after the appointment of an executive council, another meeting was called to be held at Cincinnati in September in connection with the annual meeting of the American Hospital Association. At the September meeting the organization was completed, the name being changed to the American Conference on Hospital Service. A third meeting was called, to follow the

annual conference on medical education in Chicago, in March, 1920. Beside the associations represented at this meeting in Chicago, the new association included in its membership the medical departments of the United States Army, Navy and Public Health Service. Permanent officers and a board of trustees were elected and it was decided to create several committees. The meeting in Chicago resulted in a further perfecting of the organization and the naming of the personnel of committees on hospital service and record, hospital internship, nursing and social service as related to industrial medicine. It is hoped that this organization will result in securing the cooperation of all who are interested in hospital development.

GRADUATE MEDICAL EDUCATION

During the last year, the Chairman of the Council, assisted by Dr. Louis B. Wilson, of the Mayo Foundation, Chairman of the Council's special committee on graduate medical education, inspected all but a few of the graduate medical schools of the country and their report is briefly summarized as follows:

1. Opportunities for American medical graduates to study in Europe are at present largely limited to short "courses" of lectures and clinical and laboratory demonstrations. Positions permitting individual study of, and responsibility for, the diagnosis and treatment of patients are properly filled by each country's own medical graduates.

2. In the United States opportunity for graduate study is sought (a) by those desiring to study for a few weeks or months, and (b) those desiring to study for several years.

3. The short-term graduate students,—about 6,000 this year in the United States—are (a) general practitioners seeking courses in continuation of their undergraduate studies, and (b) partially prepared specialists seeking to perfect their technic, usually in some minor surgical field.

These two classes of graduates possess the following general characteristics:

Nearly all have practices, either general or more or less special, which they cannot leave for any considerable length of time; many are inadequately trained in the fundamental medical sciences; in the brief periods they can leave their practices, they are averse to spending much time on fundamentals, and, in most instances the time at their disposal is entirely inadequate to obtain even a proper start in the fundamental subjects. Most of them desire work in operative technic in surgery. A small proportion seek to study cases for clinical diagnosis. Most wish to be "crammed" and can afford to pay a reasonable fee for instruction.

The existing postgraduate schools take almost all applicants for short terms of study, though many do not enter because they cannot get the courses desired. University medical schools should provide opportunities for the better prepared men of these classes to combine diagnosis with treatment.

4. The long term graduate students,—about 4,000 in the United States this year,—are (a) those who wish to devote two or more years to study for practice in some special field, and (b) a small number who wish to prepare themselves for public health work or for teaching or research in the fundamental branches.

Opportunities for graduate students to prepare themselves by long periods of work in the clinical specialties are woefully lacking. Opportunities for long term courses in public health or in the fundamental branches exceed the demand, but fellowship stipends and ultimate financial rewards are too small to permit many without private resources to select such fields for their life work. The remedy is an adequate endowment for student fellowships and teaching positions.

On the basis of the inspection, the committee arrived at the following conclusions: (a) That the present facilities for graduate medical work in this country are entirely inadequate. (b) That the legitimate demand for work of this kind should be met. (c) That this demand, which has heretofore been made by proprietary schools should be met by the universities. (d) That it would be desirable for 15 or 20 strong university medical departments to consider the development

of graduate medical departments. A suggested plan for such a school is as follows:

The graduate medical department should probably be independent of the under-graduate department, and with a separate faculty; an adequate teaching hospital and out-patient department; clinical laboratories for both out-patient department and hospital, and research laboratories. In addition to a general teaching hospital, it should have the control of special hospitals, such as eye, ear, nose and throat, orthopedic, infectious diseases, etc.

Provision should be made in the curriculum for at least five classes of students.

Group 1. For young men who have completed their medical course and their hospital internship, a course of probably three years, such as is given at the University of Minnesota. As far as possible these positions should be fellowships carrying with them a living salary. These students, at the satisfactory completion of their work, should be given a degree of Master of Science or Doctor of Philosophy in Surgery, Ophthalmology, or whatever specialty they have been studying.

Group 2. For men who have completed their medical course and internship and have been in practice for three to five years, a course of at least a year of special training which in addition to their practice would be the equivalent of the three year course of Group 1. These men, if they demonstrate their fitness, should be given the same degree as the men in Group 1.

Group 3. For men who have been in general or special practice a course of six months or more of training in some chosen special line. At the satisfactory completion of this work the student should be given a certificate.

Group 4. For a large group of practitioners short courses of from four or six weeks should be given in any field of work they desire. These courses should be known as practitioners' courses; they would furnish an opportunity for the practitioner to become more competent, but should not be regarded as preparing the practitioner for a specialty. No certificate of any kind should be given for this work.

Group 5. Certain courses should be planned also for practitioners who live near the medical school and could devote a few hours once or twice each week to some special subject without discontinuing their practice. This would enable practitioners to keep in touch with the newer developments in clinical and laboratory work.

As to compensation men who devote their entire time to teaching in the graduate school should be paid adequate salaries. The compensation of the clinical teachers could be met from tuition fees. In the Graduate Medical School of Harvard we were told that about 75 per cent. of the fee went to the teachers and 25 per cent. toward general expenses.

III. ELEVATING THE STANDARDS OF MEDICAL EDUCATION

The third function of the Council was to act as the agent of the American Medical Association in its efforts to elevate the standards of medical education.

Towards this end, the Council, in 1905, established an annual conference on medical education. During the last few years the conference has been held concurrently with the annual meetings of the Association of American Medical Colleges and the Federation of State Medical Boards, and has grown into an annual congress on medical education and licensure. This congress has been entirely informal and is without legal powers. Nevertheless, as an open forum in which problems of medical education and licensure have been presented and discussed, it has been of great service in elevating educational standards. We hope that the newly organized American Conference on Hospital Service will also become closely identified with this annual congress.

The congress held March 1-3, this year, in Chicago, was a most successful and instructive meeting. Over 200 delegates were present, representing not only medical educators and representatives of state licensing boards, but also presidents of prominent universities, and representatives of educational boards and foundations. Beside the usual reports of progress in medical education and licensure, the papers dealt with

special functions of state universities, full-time teachers and research in medical schools; graduate medical education in the United States and abroad; problems and inter-state relations in licensure and a series of reports on medical teaching in the preclinical branches. Among the speakers were President George E. Vincent, of the Rockefeller Foundation; Abraham Flexner, of the General Education Board; President Thwing, of Western Reserve University; President Wilbur, of Leland Stanford University, and President Jessup, of the University of Iowa.

URGENT NEEDS IN MEDICAL EDUCATION

There are three special needs which require the attention of those interested in the best medical education:

1. The age of students on graduation.
2. The financial side of medical education.
3. The development and reorganization of medical schools on sound educational lines.

THE AGE OF STUDENTS ON GRADUATION

At the annual conference held by the Council in 1917, it was shown that the average age of students on graduation and completion of the hospital year was 28 years plus. This brings the student into the practice of his profession at a far too advanced age. In Central Europe and in Great Britain, physicians enter practice at about 25 or 26 years of age. The solution seems to be to save two years of the student's time by a reorganization of the intermediate and high school curriculums. A comparison of the educational scheme in the United States with that of European countries shows that about two years of time are lost by the average student in this country during his grammar and high school courses. The student of the United States on graduation from high school, would at the same age in Europe have completed the equivalent of two years of work in our colleges of arts and sciences. Agencies in the United States having to do with high school and college education are planning to reorganize the secondary school curriculums so as to save these two years of time. This would enable the average student to graduate two years earlier from the medical school.

THE FINANCIAL SIDE OF MEDICAL EDUCATION

Many plans now under consideration for the development of medical education seem to utterly disregard the cost.

The fees of each medical student on the average are about \$150 each year, while the cost of his instruction is about \$450. In many institutions the cost is \$1,000 or more and is still mounting. With the increasing cost, fees could be raised to possibly \$250. In the interests of the whole community the cost of medical education should be kept as low as possible. For example, the cost of maintaining a hospital for medical teaching should not be borne by the medical school. No hospital should be created and maintained primarily for the teaching of medicine. The first function of a hospital is to take proper medical care of patients, and as a second function, medical teaching and research.

The use of great municipal, state and denominational hospitals should be placed at the disposal of our medical schools for teaching and research. With proper control such a combination of hospital and medical school can be of great mutual benefit. For example, the state hospitals in several states have also been made the teaching hospitals of the state university medical schools. It is pleasing to note also that in several cities—e. g., Augusta, Memphis and Louisville—city hospitals have by contract been made the teaching hospitals of local medical schools. Such combinations are in the interests of the public and receive enthusiastic and generous support. Out-patient departments likewise would serve a more useful function in the community if they were utilized for medical teaching. Special hospitals, such as maternity, orthopedic, children's, eye and ear, psychopathic, etc., should also be associated with medical teaching.

THE ALL-TIME CLINICAL FACULTY

The much discussed plan of all-time clinical teachers is so extravagant that it cannot be generally adopted by the medical schools of the country. A school without unlimited

resources could not consider it and even a school with large resources can secure better results with a given amount of money by adopting the part-time plan. The all-time clinical teacher experiment has not been encouraging and it is difficult to secure the best type of men for these positions under restrictions that exclude them from the rewards of professional work well done. It is no secret that these all-time clinical positions have gone begging and well trained clinicians have refused to accept them.

For medical schools having a reasonable endowment, the most practical plan of organizing the clinical departments would be to provide the head professor in each department with a salary of about five thousand dollars a year, and with 10 or 20 beds in the hospital which he can use for his private patients. He should be permitted to devote two hours a day to this private work and be expected to devote the necessary time to teaching duties. If a professor in a clinical chair abused his privileges it would be easy to correct or eliminate him. Living salaries also should be paid to associates; younger men who would do the bulk of the teaching and clinical research. Their greater compensation is the educational opportunity by which after a few years they can become masters of the science and art of medicine and be able to enter successfully into the practice of their specialties. This plan is not an experiment but has been gradually developed after years of experience in the medical departments of the best universities of the world.

REORGANIZATION OF MEDICAL EDUCATION

Some weaknesses have developed in the process of changing our old type of medical schools into medical departments of universities. In the transition the laboratory branches of the medical course have been placed in the hands of university professors who are not in close touch with the practice of medicine and the medical profession. As a consequence,—and as shown by the testing of medical education in the war,—the laboratory branches are not being well taught, even in our best schools, from the standpoint of the training of practitioners of medicine. The college professors of anatomy and physiology have many of them drifted from the science and practice of medicine and from the medical profession.

The American Association of Anatomists, composed largely of the teachers of anatomy in medical schools, is no longer affiliated with medicine. Its meetings are largely devoted to scientific discussions of the embryology of the rat and lower forms of life and have little or no relation to the science and art of medicine. In many medical schools splendid courses in embryology and comparative anatomy are given but applied human anatomy which is an every day necessity to the practitioner of medicine, is not taught. The college professor of anatomy is sometimes incompetent to teach it and as a result the students suffer. Men of the non-medical type have no place as teachers of anatomy in a medical school and their places should be filled by men who have had a complete medical training. Their first duty is to train practitioners of medicine.

SOME WRONG TENDENCIES IN CLINICAL TEACHING

Medicine passes through cycles. In Trousseau's time, in 1860-1870, the chemists thought chemistry would solve all medical problems, and Trousseau in a clinical lecture pointed out the fallacies of their claims. The same place in the cycle has returned and the chemists and laboratory workers are again claiming that all medical problems are to be solved by the chemical route. To many of these men, the older methods of physical examination, careful clinical observation and morbid anatomy, are old and worn out things in the light of the newer medical chemistry. And some of these men have succeeded in so impressing university trustees, that men who have had special training only along chemical lines are being appointed to chairs of medicine rather than men with a broad clinical training. This tendency is not in the best interests of medical education, of the medical profession, or of the patient.

Sir James Mackenzie in his recently published book on the future of medicine has done a real service in calling attention to the great importance of clinical research along the broad

lines of the clinical observation of the patient and the attempt to properly interpret from the symptoms and history the pathology in the case.

SOME TENDENCIES IN OUR MEDICAL SCHOOLS

At present in this country the university professors in the laboratory branches have been given too large a part in reorganizing our university medical schools and in developing the medical curriculum. It is clearly our duty to call attention to this fact and see that this tendency is corrected. The first and highest duty of the medical school is to train competent practitioners of medicine and this cannot be done by the college professor of embryology and comparative anatomy, or by the chemist working in a clinical laboratory or by the research worker in some isolated medical institute. This problem is to be met by placing the reorganization of medical education in the hands of medical men.

1. The teachers of the laboratory branches should be required to have a medical training which would give them a medical point of view; they would keep in touch with the art and science of medicine, and would realize that their first duty was to assist in training practitioners of medicine.

2. The teachers of the clinical branches should have a broad medical training in both the science and the art of medicine; they should be great clinicians in their special fields, who understand not only what anatomy and physiology, pathology and pharmacology the student needs to acquire, but also what he needs to know to become an expert practitioner of medicine. Fortunately in the last twenty years many such men have been trained in this country.

The controlling element of a medical faculty must consist of a group of medical men in the closest touch with the science and art of medicine and with the medical profession. Such a group must have as its members the professors of medicine, surgery, obstetrics and pathology. Such a group must control a teaching hospital and an out-patient department, with adequate clinical and pathologic material and well equipped laboratories. This plant should be located where it can secure ample clinical material with little or no cost to the medical school.

There is no desire to belittle the importance of the laboratory branches in medicine. But a medical school is a school in which to train doctors and not anatomists or physiologists. If it fulfills its first and most important function, the training of practitioners of medicine, it will also be training teachers and research workers.

SUMMARY

This report is summarized as follows:

(a) Instead of 162 medical colleges which existed in 1904—over half the world's supply—this country now has 86, the character of which has been greatly improved. Instead of only 3 per cent. in 1904 requiring two or more years of college work for admission now 92 per cent. have that standard.

(b) The lowest ebb in the enrolment of medical students, due to the adoption of higher entrance qualifications, was 13,052 students in 1918-19. An estimate shows that the enrolment in the present session is 13,554 students. The increased enrolments of premedical students show that the classes in medical schools will continue to increase at least during the next several years.

(c) The trend of medical schools to limit their enrolments of medical students is in the interests of better medical education. Even with this limitation, the capacity of Class A medical schools is sufficient to care for many more than are at present enrolled in medical schools and this capacity can be easily expanded to meet future needs.

(d) With the higher standards adopted during the last sixteen years the requirements for admission to medical schools in the United States are now on a par with other leading countries.

(e) The American scheme of premedical education is of particular advantage in that a student can postpone his final selection of the medical profession until he is best qualified to make that choice.

(f) Hospital internships are voluntarily obtained by a great majority of medical graduates. An internship has been

made an essential qualification for the license in ten states. It has been adopted as an essential for the degree by eleven medical schools.

(g) The present demand for hospital internships could not be met even if the number of medical schools and the number of graduates each year should be doubled or trebled—a measure not necessary to meet the normal demand for physicians.

(h) The hospital intern problem may be solved by (a) extending the internship to two years; (b) employing resident physicians; (c) training assistants or nurses to do much of the work now devolving on interns; (d) having stenographers take down histories from dictation at the time staff members examine patients.

(i) There is no scarcity of physicians in the United States; there is, however, an imperfect distribution of the present supply. Medical care in rural communities is improving rapidly with better roads, automobiles, etc., by which services of physicians in nearby cities may be more readily secured.

(j) A re-inspection of all medical colleges is being made by the Council preparatory to a revision of the classification of medical schools. This re-survey is also revealing many improvements as compared with conditions found in 1906.

IMPROVING HOSPITAL SERVICE

(k) The improving of hospital service is now one of the most important works confronting the medical profession. It is a work in which, naturally, physicians are most largely concerned. The American Medical Association, therefore, should take an active part in this work.

(l) The work of the Association in connection with hospitals has rapidly grown since 1903. Under the Council on Medical Education there is now a Bureau on Hospitals with a man who devotes his entire time to the work. With the rapidly increased interest in hospital development during the last few years the work has been correspondingly extended.

(m) Besides the collecting of hospital information each biennium for the American medical directory, more elaborate surveys of all hospitals were made in 1912-14, and in 1915-16. A third extensive survey is now in progress.

(n) An advisory committee on hospitals to cooperate with the Council has been appointed by every state medical association. These committees are doing splendid work and several have undertaken the personal inspection of all hospitals in their states.

(o) The Association should continue to (a) conduct a clearing house of hospital information; (b) further develop the Hospital Service Department in *THE JOURNAL*; (c) perpetuate its indexes and classifications; (d) inspect hospitals where satisfactory information is not otherwise obtained; (e) create permanent hospital committees in all states; (f) develop closer relationship with individual hospitals; (g) cooperate with other agencies working for better hospital service.

(p) An organization known as the American Conference on Hospital Service has been created at the suggestion of the Council on Medical Education in which the various agencies interested in hospitals are represented. The first meeting was held at the American Medical Association headquarters, Chicago, April 21, 1919. Subsequent meetings for the completion of organization were held in Cincinnati, September 9-10, 1919, and again in Chicago, March 3-4, 1920.

NEEDED IMPROVEMENTS IN MEDICAL EDUCATION

(q) There is great need in this country of increased and improved facilities for graduate medical education. This need could be best supplied by our leading university medical departments.

(r) Efforts should be continued to so rearrange educational methods that the average age of medical graduates may be reduced by at least two years. The solution now seems to be in a reorganization of intermediate and high school education.

(s) The extravagant and unnecessary expenditure of money in the development of medical education should be deprecated. In some recent plans for development this point seems to have been utterly disregarded.

(t) There is a serious tendency in present day medical education to drift into the ultra-scientific and to ignore or belittle the development of a closer relationship of the pre-clinical and clinical branches. This tendency will be decreased if it is required that teachers of the laboratory departments in medical schools shall have had a complete medical training by which they will obtain the medical point of view.

Respectfully submitted,

COUNCIL ON MEDICAL EDUCATION.
ARTHUR DEAN BEVAN, Chairman,

ROBERT C. COFFEY,
WILLIAM D. HAGGARD,
ISADORE DYER,

WILLIAM PEPPER,
N. P. COLWELL, Secretary.

Report of the Council on Scientific Assembly

Dr. J. S. Horsley, Virginia, Chairman, presented the report of the Council on Scientific Assembly, which was referred to the Reference Committee on Sections and Section Work. The report follows:

To the Members of the House of Delegates of the American Medical Association:

Shortly before the adjournment of the final meeting of the House of Delegates at Atlantic City, the following preamble and resolution were submitted by the delegate from the Section on Obstetrics, Gynecology and Abdominal Surgery:

WHEREAS: An effort is being made to organize an international Congress of Obstetricians and Gynecologists at a meeting in Brussels during September next, at which American Obstetricians and Gynecologists will have representation, therefore, be it

Resolved, That the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association unanimously approves of this movement, stands ready to cooperate in every way, and cordially invites the Congress to hold its initial meeting in New York at a convenient date to be determined.

The House received and referred this communication to the Council on Scientific Assembly but it did not empower the Council to act in this particular matter which does not fall within the scope of the Council as it is defined in the By-Laws of the Association. Consequently, the Council respectfully reports that it has taken no action.

On January 10, the Council held a conference with the secretaries of the sections at the headquarters of the Association. All the sections were represented either by their secretaries or one of the other executive officers. All the members of the Council were present except Dr. Roger S. Morris, who was absent on account of serious illness. In compliance with the Standing Rules of the House of Delegates for the guidance of the Council on Scientific Assembly, and with unanimous consent of all in attendance at the conference, arrangements were made so that each section will hold one meeting on each of the days assigned for section meetings during the 1920 annual session. Seven sections will convene each morning at 9 o'clock as follows: Surgery, General and Abdominal; Ophthalmology; Diseases of Children; Pharmacology and Therapeutics; Nervous and Mental Diseases; Preventive Medicine and Public Health, and Urology. Eight sections will convene each afternoon at 2 o'clock as follows: Practice of Medicine; Obstetrics, Gynecology and Abdominal Surgery; Laryngology, Otology and Rhinology; Pathology and Physiology; Stomatology; Dermatology; Orthopedic Surgery, and Gastro-Enterology and Proctology. It will be noted that most of the sections which at the 1919 annual session met during the morning hours, this year will hold their meetings in the afternoon hours, and that the majority of the sections which met last year in the afternoon hours will meet this year in the mornings.

The Council appreciates the interest and hearty cooperation manifested by the section officers who attended this conference. In the opinion of the Council this has made it possible to provide a well balanced scientific program for the entire Scientific Assembly—a program which will be interesting and instructive to all the Fellows who attend the annual session and yet one which maintains or improves the scientific standards of the sections.

In the development of its work, the Council has come to the point where it feels that its effectiveness would be

increased if it were constituted in a somewhat different manner than that now defined in the By-Laws. Consequently, the Council asks that it shall be reorganized so that it shall consist of five appointed members and shall have associated with it, ex-officio, the President-Elect of the Scientific Assembly, the Editor of THE JOURNAL and the Secretary of the Association. The members of the Council desire also to emphasize the value to the Council of the experience which members have gained from serving as section officers. The Council recommends that Section 7, Chapter VII of the By-Laws shall be amended so as to provide for the changes in the composition of the Council which have been suggested and to define the functions of the Council as follows:

The function of the Council on Scientific Assembly shall be: (1) To secure cooperation between the sections. (2) To pass upon questions of policy in relation to section work. (3) To stimulate the development of the sections. (4) To consider at first hand applications for new sections, or for changes in existing sections, and to report to the House of Delegates. (5) To assign and to appoint officers for the meetings of the section on miscellaneous topics. (6) To arrange the programs for the general meetings of the Scientific Assembly.

At the last annual session of the House of Delegates, the Section on Dermatology requested that the title of that section be changed to the "Section on Dermatology and Syphilology." As this is a question of policy in relation to section work, and also is a change in the existing sections, the matter has been brought to the attention of the Council, and after giving the subject careful consideration, the Council recommends that the request of the Section on Dermatology be complied with, and that Section 1, Chapter IX of the By-Laws be amended by substituting for the present Item 11 in that section reading "Dermatology" the words "Dermatology and Syphilology."

In compliance with the suggestions offered at the conference of secretaries of sections, in order to make the statement more definite, the Council recommends that Section 11, Chapter XI of the By-Laws shall be amended by substituting for the present wording of the section the following:

SEC. 11.—LENGTH OF PAPERS AND DISCUSSIONS.—The time allowed for the presentation of a paper before a section shall be limited to fifteen minutes. No one shall discuss any paper more than once, nor for longer than five minutes except with the unanimous consent of those present.

In order to clarify the meaning of Section 5, Chapter XI, it is recommended that the section be amended by adding at the end of the second sentence the words "of the section," so that the section shall read:

SEC. 5.—EXECUTIVE COMMITTEE.—Each section shall have an executive committee, which shall consist of the last three retiring chairmen. In case of absence of a member of the executive committee from a Scientific Assembly, the vacancy shall be filled by the chairman of the section. This committee (as constituted at the close of the Scientific Assembly) shall examine and pass on all papers read before the section, and shall endorse for publication only those that are of scientific or of practical value, and which will reflect credit on the section before which they were read.

Respectfully submitted,

J. SHELTON HORSLEY, Chairman,

E. S. JUDD,

F. P. GENGENBACH,

ALEXANDER R. CRAIG.

Report of Committee on Red Cross Medical Work

Dr. C. W. Richardson, Chairman, presented the report of the Committee on Red Cross Medical Work, which was referred to the Reference Committee on Reports of Officers.

The report follows:

To the Members of the House of Delegates of the American Medical Association:

The Committee on Red Cross Medical Work wishes to report that having put itself in relationship with the American Red Cross, it found that the American Red Cross decided it was useless to call a meeting of the committee, or to put it into action this year on account of the cessation of the war, and that no further need of general action between the Red Cross and the American Medical Association existed. The committee requests therefore, that it be discharged.

Respectfully submitted,

CHARLES W. RICHARDSON, Chairman,
CHARLES R. REYNOLDS, JOEL T. BOONE.

ADDENDUM

(Insert page 1232, Preceding Reports of Officers)

Dr. J. Voncken of Belgium was introduced and through the Speaker thanked the delegates for his warm reception and expressed his pleasure at being present.

The Vice-Speaker, Dr. Dwight H. Murray, New York, took the Chair, after which the Speaker delivered an address, which was referred to the Reference Committee on Reports of Officers.

Address of the Speaker, Dr. Hubert Work

To the House of Delegates:

Again it is my pleasure to convene this body of selectmen, from the membership of the American Medical Association.

By common consent, reduced to Constitution and By-Laws, this House of Delegates is the governing branch of the Association—the machinery which correlates the scientific product of the annual meetings. You work under articles of government which you amend or abrogate at will. No coordinate branch of the Association may direct or compel, beyond your pleasure. All of its officers are elected and their duties defined by you.

This recapitulation is intended to recall to mind your prerogatives and responsibilities in the art of government.

CONSTITUTIONAL CHANGES

The Judicial Council in its report now in your hands, has made recommendations for changes in the Constitution and By-Laws, for your consideration and action. In the main the changes consist of reconstruction of the text for the purpose of clarity, with the deletion of all matter relating to the Committee on Red Cross Medical Work, also of the text referring to the Ad Interim Committee, with minor changes.

THE AD INTERIM COMMITTEE

The purpose of the Ad Interim Committee, designed to act for the House of Delegates in emergency, was well conceived.

Its predetermined personnel was probably unfortunate. Authority for quick action should be vested in a small, wieldy body of Fellows for emergency service. If this committee be continued, it should, I believe, consist of the Speaker, the Secretary, and three sitting members of the House, to be elected annually. As now constituted the Ad Interim Committee includes the President of the Board of Trustees and imposes interlocking duties on him. Ex-presidents of the Scientific Assembly may lapse their interest in the Association. Certainly their official responsibilities have passed.

The President and President-Elect are not subject to the House of Delegates, so that four of the seven members of this committee as now constituted to act for the House, are not responsive to it, while the dual allegiance of the President of the Board of Trustees embarrasses him.

A substitute for the existing Ad Interim Committee may be provided by delegating its prescribed emergency duties to the Board of Trustees, or to the Executive Committee of the board, as you may determine. Argument that this might concentrate power would be valid. However, it would pass to officers whose acts are subject to review by the House.

The new By-Laws propose that the Speaker shall nominate members of the Standing Committees, presumably because of his more intimate knowledge of the qualifications of Fellows and of the duties of these councils, which come directly under the jurisdiction of the House. Heretofore members of these committees have been nominated by the president of the Scientific Assembly, whose term of office ends one year thereafter and four years before that of his appointees.

A suggestion well worth considering but not recited in the proposed amendments, is that of reducing the number of Trustees of the Association to seven or five members; the subdivision of the United States into trustee districts, and

the lengthening of their term of office, perhaps coupled with a prohibition against reelection, at least until after one year has intervened.

This suggestion implies a substantial reduction in the operating expenses of the board and need not endanger its working efficiency.

To limit the number of board members, implies concentration of authority, but at the same time, to fix a limit to their continuous service, would preclude the very remote possibility of self-perpetuation and would bring to the board, each year, a new member directly from the profession without.

The further suggestion for a districting of the United States, if approved, would avoid the election of two or more Trustees from a circumscribed, undefined section, and would result in as wide geographic representation on the Board of Trustees as we now have.

The relations of this House to the Assembly of the Scientific sections become more clearly defined each year. Inasmuch as the House is the executive of the Scientific Assembly, including the election of its officers, it would appear that all section units of the Scientific Assembly should indicate by nomination to the House, those whom they would approve for the presidency and vice presidency of the Scientific Assembly. This plan, if adopted, would afford each section an opportunity to compliment members who had distinguished themselves, and at the same time put before the House many potential presidents, for consideration, both for immediate and subsequent elections.

DEPARTMENT OF PUBLIC HEALTH

Our Association should again address itself to procuring a separate governmental department of public health. The public mind has been prepared for it by the exigencies of the late war. Health service is not logically a part of the national treasurer's duties, nor the Surgeon-General properly subordinated to the Adjutant-General of the Army. This is not a new subject to you but an old ambition which can now be revived with more than reasonable assurance, but preferably from different angles of approach. A concurrent resolution preliminary to such action, recently made favorable progress in Congress, but as heretofore, has failed because of the limitations of individual sponsors.

Those favorable to government supervision of the public health, through a separate department created for that purpose, now hold, or are aspiring to high office. It is possible that the influence of our 80,000 members exerted on our Congressmen at home, with powerful influence reaching from above them in Washington, may become effective.

THE ART OF MEDICINE

At one time physicians were said to practice the art and science of medicine. The art of medicine is the applying of its science; the selling of the science of medicine, if you please. It comprehends the refinement of the little things in practice and dictates the treatment of the patient. Homeopaths cast the future of their practice on it and popularized their dogma. The Christian scientists, likewise all quacks, thrive through attention to an art once attached, but now largely lost, to internal medicine, but which has been developed by surgeons, independently.

Masters of great clinics are famed for their art in organization and the results attained, partly through the consciousness of the patient. The present status of sanitation and of preventive medicine as a whole falls within the Art of Medicine primarily, and its world-wide acceptance supports the argument.

This is not a plea for less Science in medicine, but for more Art; for a development of the latter, *pari passu* with the former; for the symmetrical development of ethical medicine; for its protection against the cults which practice the Arts of Medicine without its Science; from the charge that it is becoming a trade-science, neglectful of the psychic sensibilities, the observance of which distinguishes our profession from veterinary medicine.

Doubtless the greatest immediate menace to public confidence in ethical medicine is pending through isolated, operative surgery in unscrupulous hands. Unless the Art of Surgery can be re-associated with the Science of Medicine and their interdependence again established, the morale of surgeons will necessarily suffer, since the quickest diagnosis can be made by exposing the suspected organ. But the rights of the patient may have been violated. This is a real danger and not a groundless alarm. The remedy for it logically lies in the hands of the American College of Surgeons, together with others who are surgeons first and operators afterward.

MILITARY TRAINING

The vexed question of Compulsory Military Training has been confused by Members of Congress and personal campaigners until the public apparently believes that Universal Military Training would invite war, but without it, the country would be safe.

Congressmen, alarmed by our mounting cost of government; ex-service men who resented the draft; timid women lacking the spirit of the great American mother; pacifists and conscientious objectors unite in protest against it.

If the public could realize that 35 per cent. of our young men of draft age were disqualified for military service in the World War because of physical defects, and logically also for effective citizenship, the opportunity afforded in training for correcting these defects, the leveling influence of contact between young men from every social station. Furthermore, that physical correction, mental development and vocational training are the objects sought and that instruction in the Manual of Arms is the least concern of those who favor this free summer school for boys; perhaps the narrowed vision of these thoughtless objectors would expand. This duty also appears to fall within the province of physicians, patiently to lead the public toward that which is best for it.

IN MEMORIAM

Since we last met three of our members have answered their last roll call.

Floyd M. Crandall; of keen intellect, industrious, of pleasing personality and absolute loyalty to the highest ideals in medicine, died as he had lived, serene and unafraid. He was the supervising architect of our Association's laws. All changes for many years were reviewed by him. Our code of professional morals is couched in his language, and will live afterward. Those who knew him best admired him most. Nothing was too troublesome for him to do for a friend or for his profession. Reward was to him an incident and expressed appreciation an embarrassment. We can go forward without him but not so far, nor so safely.

E. C. Cantrell, for many years a trustee with floor privileges, followed by active service as a delegate in this House, fell in service to his profession. He heard the call of his country intended for younger men. He answered it and rendered distinguished service as an officer. When his uniform was mended and folded and put away, he heard another call for help. The sea-wall of his state had failed and people perished. It was his summons from beyond the Great Divide, and he, too, stepped out into the night, searching for the lost trail. Worn by volunteer service to his country and exhausted by voluntary service far outside of his community responsibilities, he did not die; he was overwhelmed.

Clinton P. Meriwether, with partially restored health, found his greatest usefulness in the later years of his life; to this Association, to his profession and to his country at war. He fought the battle of life with his nemesis beside him. It walked with him, sat down with him to dine, slept with him and eventually slew him. But never, did his great courage fail nor his step falter. And when the shadow of his life was merged into the darker shadow of the Valley, "with a cheery smile and a wave of the hand he wandered into an unknown land."

Three upright, tried and true physicians. We are proud that we knew them, and comforted by the belief that the light everlasting is falling on the upturned faces of these men.

Reference Committees

The Speaker resumed the Chair and announced the following Reference Committees:

SECTIONS AND SECTION WORK

Hugh T. Patrick, Chairman	Illinois
Lee Masten Francis	New York
Frank E. McCullough	U. S. Navy
S. R. Roberts	Georgia
Southgate Leigh	Virginia

RULES AND ORDER OF BUSINESS

W. R. Bathurst	Arkansas
John S. Helms	Florida
W. S. Lindsay	Kansas
E. A. Pray	North Dakota
Leroy Long, Chairman	Oklahoma

MEDICAL EDUCATION

J. H. Hall, Chairman	Colorado
W. H. Seeman	Louisiana
Frederic E. Sondern	New York
L. Hektoen	Illinois
F. F. Russell	U. S. Army

LEGISLATION AND PUBLIC RELATIONS

Franklin E. Murphy	Missouri
J. E. Lane	Connecticut
S. E. Lambert	Washington
J. H. J. Upham, Chairman	Ohio
Le Roy Crummer	Nebraska

HYGIENE AND PUBLIC HEALTH

J. W. Schereschewsky, Chairman	U. S. P. H. S.
A. T. McCormack	Kentucky
C. Van Zwalenburg	California
J. W. Flinn	Arizona
C. St. Clair Drake	Illinois

AMENDMENTS TO CONSTITUTION AND BY-LAWS

W. B. Russ	Texas
E. A. Hines	South Carolina
Albert E. Bulson, Jr.	Indiana
Edward Heckel	Pennsylvania
Rock Sleyster, Chairman	Wisconsin

REPORT OF OFFICERS

Thos. S. Cullen, Chairman	Maryland
F. B. Lund	Massachusetts
Homan Taylor	Texas
B. R. McClellan	Ohio
C. R. Odgen	West Virginia

CREDENTIALS

S. W. Welch	Alabama
Jos. M. Aikin	Nebraska
J. B. Gibby, Chairman	Pennsylvania
John C. Rockafellow	Iowa
D. E. Sullivan	New Hampshire

MISCELLANEOUS BUSINESS

C. J. Whalen	Illinois
T. H. Halsted	New York
Geo. E. Reading	New Jersey
J. W. Bell	Minnesota
F. C. Warnshuis	Michigan
C. E. Humiston, Chairman	Illinois

Dr. John D. McLean, Pennsylvania, rose to a point of order. He stated that the Speaker had authority to nominate members for Reference Committees, but they were to be elected by the House.

The Speaker stated that he had authority to appoint the Reference Committee, and the Committees so appointed, and announced would stand unless the House decided otherwise.

Dr. A. T. McCormack, Kentucky, moved that the members of the various Reference Committees as nominated by the Speaker be elected.

Seconded and carried.

The next in order was an address by Admiral William C. Braisted, U. S. Navy, President-Elect of the Association.

The Speaker stated that Admiral Braisted had requested the privilege of addressing the House after his induction into office, which request was granted.

Report of Secretary

The Secretary presented his report, which was referred to the Reference Committee on Reports of Officers. (See page 1232.)

Address of Dr. Alexander Lambert

The President of the Association, Dr. Alexander Lambert, New York City, delivered an address which was referred to the Reference Committee on Reports of Officers:

For a number of years there has been slowly developing a realization of the influence and value of hospitals as institutions. It is also evident that the rapidity of the growth of these institutions and the amount of benefit to be derived from them depends on the development of many different interests which are focused in each hospital, making it an institution and not merely a shelter in which the sick may rest and recover.

As a modern development nursing came first and then the beginnings of modern surgery followed by the practical application of preventive medicine causing the separation of communicable diseases from the general wards. Then followed the development of the social service side of the institution through which the great human relationship of the sick and injured was not lost sight of when they entered the hospital. Through which also the care and treatment of the sick and injured did not cease when they left the hospital, but continued with therapeutic intent out into their daily environment. It soon developed in the minds of the surgical side of the profession, as the great possibilities of modern surgery were unfolded, that the best surgical technic could not be brought to perfection without a tremendous development in the hospital as an institution in which all the multiple details of the best surgical technic could be obtained. To bring this about required a standardization and development of hospital organization itself. The development of all medicine under the expanding influence of scientific research forced, as necessities, into the hospitals, several kinds of laboratories such as roentgen ray, chemical and pathological.

Simultaneously with this technical growth within the hospital, medical education has developed and coincidentally it became increasingly evident that the future development of the medical school and the hospital were inseparably linked together. It was further noticeable that on the one hand the most painstaking care of the sick and injured was carried out in the hospitals connected with the medical schools and on the other hand the medical schools needed the biggest hospital opportunities. The executive side of the management of the hospital, of course, endeavored to keep pace with the development in the technical or medical side, and it was soon evident that it required a combination of medical and executive ability to run to the best advantages a large hospital, and required the vigorous energy of able-minded trustees to manage the institution as a whole and keep it in existence as an endowed or a self-supporting institution.

The activities of all these various interests centered in the hospital could not proceed without the various societies back of the individuals engaged being equally interested in a subject of such importance. About a year ago, at the call of the President of the American Medical Association, a meeting was held at which it was decided to hold a conference of the societies interested in hospitals, and representatives from the following societies were invited to meet together in September, in Cincinnati:

American Association of Industrial Physicians and Surgeons.

American Association of Hospital Social Service Workers.

American College of Surgeons.

American Hospital Association.

American Medical Association.

American Nurses' Association.

Association of American Medical Colleges.

Catholic Hospital Association of the United States.

Federation of State Medical Boards of the United States.

International Compensation Board.

National League of Nursing Education.

National Organization for Public Health Nursing.

The Medical Departments of the Army and Navy and the U. S. Public Health Service.

At the Cincinnati meeting a permanent conference was organized to meet regularly as a forum for the discussion

and development of the common interests. The separate societies here represented have in the past through misunderstanding and through lack of knowledge of one another's aims, failed to coordinate and have instead often produced discord and brought about results injurious to the best development of the hospital as an institution. It is only through the continuous mutual education of the various groups that the necessary knowledge of what a hospital should be in a community can be developed in the minds of those most interested in hospital work. No individual group of the hospital conference is at present capable of developing the hospitals of this country as they should be developed.

The subject is of such great and constantly increasing importance to the medical profession that it is time the American Medical Association should take cognizance by special action of a subject of such vital interest to its members and should lend its support and influence through definite and continued action. Such action in the American Medical Association can only be brought about through the existence of a standing committee, formed as are the other councils of the American Medical Association.

In the first place the question arises whether or not a new council should be formed or a bureau developed under some existing council. Of the existing councils, the Judicial Council does not come under consideration. Questions of hospital management and development should not be placed among its duties. There is already existing a Bureau of Hospitals under the Council on Medical Education, a report on which is in the handbook at present before you. The activities of this bureau are built around the interests of medical education and the instruction of interns, and its information largely gathered from interns in the hospitals and from those interested in hospitals in the relation to the intern. This bureau has collected and possesses a tremendous amount of information not yet tabulated and at present, therefore, useless, which is not directly of interest in the relation of medical education or the internships, but as soon as tabulated it will be of enormous value to the profession for their information regarding the general situation in hospitals.

Hospitals having interns comprise probably 20 per cent. of all the hospitals in the country. Eighty per cent. of the smaller hospitals scattered through the country will, in all probability, never be able to obtain interns and yet in the mass these must be depended on to give the greatest amount of care to the sick and injured of the country.

One realizes as one reads this report of the Council on Medical Education that the entire hospital situation has been considered solely on the narrow line of rendering hospitals centers for postgraduate training of prospective doctors and the larger aspect of the hospital problem of having the hospitals serve their communities as vital centers in the protection of the population as well as places in which the sick may be cared for is completely ignored.

In reading the report the impression might be gained that the American Medical Association intended to attempt to dominate the entire hospital situation, and domination at the present time is not what is desirable when cooperation is essential to success.

The plan as outlined corresponds exactly to what has been done in regard to medical schools and has worked well in solving this problem, but the hospital question is more extended than that of medical schools, and any attempt to classify hospitals along the single line of whether they possess interns or not does not meet the exigencies of the problem at all, but would be sure to create an antagonism, whether just or not. The Bureau of Hospitals, therefore, should not be under the Council of Medical Education and cannot so be without great injury to the smaller hospitals and without causing incessant antagonism and injury to the medical profession throughout the entire United States. Should it be, however, under the Council on Health and Public Instruction? It is possible for this House of Delegates so to transfer it if in their wisdom they see fit. A committee on hospitals can be formed by the Council on Health and Public Instruction without further action or change in the By-Laws, since

this Council has power to form committees, and it is so stated in the By-Laws.

Can you obtain the best men in the profession to work as a subordinate committee in a bureau under another committee? For such must be the line of communication to the House of Delegates for any definite plans that any bureau on hospitals may care to submit, provided that there are no differences of opinion regarding the carrying out of these plans. The hospital situation in the country is of such great importance that the responsibility for it and for the action of the American Medical Association concerning it must, it would seem, be taken by the House of Delegates itself and the group of men acting for it must have direct and unobstructed access to it at all times to obtain the sanction of the House for its plans for the development of a subject so large and important, reporting of course, as all the councils do, to the Board of Trustees between the meetings of the House of Delegates. It seems, therefore, that the customary action of the House of Delegates should be followed in dealing with a subject that is of great importance and which is bound to grow in this importance and to continue for a long period of time, that is, to form a standing committee to care for the interest of the Association in the matter and to work in cooperation and harmony with all other interests and other societies acting in the same field. It would seem to be wise, therefore, that a new council, and not a bureau under one of the present councils, should be formed to take charge of this subject.

Among the other reasons given in the discussion which has developed up to this time, it is said that there are already too many councils, and also that the American Medical Association could not afford it. In the first place that there are too many councils already, or that to add a new council will make too many, is equivalent to saying that the American Medical Association must take up no further interests; it must be satisfied to be limited in its public interest to preventive medicine and to medical education and that in the further growth of the nation and in the growth of the social conscience of the community for the care of its sick or in other future development or interests of the medical profession, the American Medical Association shall take no further part. Such a view, gentlemen, comes only when men look back at the end of successful careers and cease to look forward. It is not the thought of the vigorous years of life. That the American Medical Association cannot afford to bring into existence a new council on hospitals, but can continue a bureau on hospitals is hardly consistent logic, because the main expense of such a Council is practically connected with the carrying on of an efficient bureau and expanding the efficiency and developing the knowledge already obtained in the present bureau—in short, developing broadly what has already been so well begun.

There is no question that the American Medical Association cannot afford at present to spend great sums in any new direction; neither are great sums here required, particularly since the societies outside the American Medical Association interested in hospital development are not asking nor expecting nor desiring the American Medical Association to shoulder the main expense in the development of the hospital situation. They do expect cooperation and assistance from the American Medical Association, and that cooperation can well be defined and be effective under small expense. The American Medical Association cannot afford to refuse to meet half way these many hospital interests in the development of this great public and professional need. The expense, if properly managed, unquestionably should not be greater than could have been safely borne by the American Medical Association during the last year, and the future outlook of the American Medical Association justifies the adventure.

The advice of the following gentlemen was sought on the hospital situation: Drs. W. J. Mayo, John M. Dodson, Richard C. Cabot, Adrian V. S. Lambert and A. R. Warner. There was no formation of these gentlemen as a committee nor meetings as a committee, but the request was made that they should act as advisers to the President. It is evident

from their communications that in their opinion coordination between the American Medical Association and the other societies, as already mentioned, as represented in the American Conference on Hospital Service is essential for the best development of the hospital situation in the United States. The question of whether this should be done through a bureau in an already existing council of the American Medical Association or through a newly formed council on hospitals brings out differences of opinion. On the one hand, it is believed that the best cooperation can be obtained and the most effective work can be done through a council, rather than a bureau. On the other hand, it was bluntly stated that the other societies in the conference were eager for the cooperation of the American Medical Association but were jealous lest the cooperation should turn into an attempted domination by the largest society, and this was feared and would surely be resented. The discord and antagonism between the College of Surgeons and the American Medical Association was considered so deplorable that everything should be done to bring about its cessation and every endeavor must be exercised to prevent its increase and continuance.

There is a strong feeling among the other societies that a bureau of the American Medical Association under an existing council, as Health and Public Instruction, would create less antagonism than if a separate council were formed. The greatest antagonism of all would arise if the bureau were continued under the Council on Medical Education, since it is believed that the interest of medical education and of interns often runs counter to that of the smaller hospitals. The majority of opinion, however, favors the formation of a separate council rather than a bureau.

The belief has been confidently expressed that though working together in a common interest, mutual confidence and cooperation would soon replace distrust.

In considering the cooperation of various societies interested in hospital work, it seems beyond question that the best results will be obtained if each society continues to be responsible for that special hospital function in which it already has shown the predominant activity. That is, the American Medical Association to continue the predominant guidance of medical education and all matters relating to hospital interns; the College of Surgeons to continue the development of hospital standardization and hospital records, and concentrate its energies therein; the American Hospital Association to develop the administrative functions of hospitals and furnish to all concerned the information required for all physical needs of hospitals. No one group can master all these subjects, and no group should confine its interest to any one subject; but through mutual committees and exchange of information, all facts obtained by each should be forwarded to the other groups to be the common property and knowledge of all. The questions of the future development of nursing and the education of nurses press for solution, and the medical profession must do its share to solve the problems here presented and not stand aloof as it has done in the past. Occupational therapy and the reconstruction of the injured that they may obtain the greatest economic returns from their handicapped existence are new points of view to be reckoned with in estimating the value of the end-results of hospital work. The social service division in hospitals has won for itself recognition as a necessity in hospital responsibility to the patient. It has developed among the laity with tremendous rapidity; but, curiously enough, has won its position in the hospitals not so much against the opposition of the medical profession as it has in spite of the studied and unintelligent indifference of the majority of hospital staffs.

The American Medical Association contains among its Fellows many who are interested in all the various hospital activities, and it is the only society possessing men especially interested in the medical side of the care of the sick as contrasted with the surgical care. It most effectively can supervise the development of the hospital from the standpoint of what is best for the sick individual coming to regain his lost health.

The American Medical Association should not limit its interest to the activities of a bureau under medical teaching

or care of interns, or limit its interest in any way. The responsibilities of the medical profession in the future development of hospitals are as extensive as the hospital activities. The responsibility of the American Medical Association to its members is also equally broad. The American Medical Association can ill afford to neglect its opportunities to assist in the growth of hospital development, nor to refuse to cooperate with all the other societies interested therein. It would seem, therefore, that the interests of the American Medical Association in its relation to hospital development will best be conserved by the appointment of a standing committee on hospitals, and it is recommended that the House of Delegates create a Council on Hospitals and amend the By-Laws to this effect.

Memorial Resolution

Dr. A. T. McCormack, Kentucky, moved that when the House adjourns, it adjourn in honor of the memories of Dr. Emory Marvel, Atlantic City, N. J.; Dr. E. E. Southard, Boston, Mass.; Dr. Floyd M. Crandall, New York, N. Y.; Dr. C. E. Cantrell, Greenville, Tex.; Dr. C. P. Merriweather, Little Rock, Ark.; Dr. K. A. J. Mackenzie, Portland, Ore.; Dr. Abraham Jacobi, New York, N. Y.

Seconded and carried.

Report of the Board of Trustees

Dr. Philip Marvel, New Jersey, Chairman, presented the report of the Board of Trustees. He also presented a supplementary report, both of which were referred to the Reference Committee on Reports of Officers. (See page 1233.)

Report of the Judicial Council

Dr. M. L. Harris, Illinois, Chairman, presented the report of the Judicial Council, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws. (See page 1238.)

Report of Council on Health and Public Instruction

The report of the Council on Health and Public Instruction was called for. Dr. Victor C. Vaughan, Michigan, Chairman, requested the Secretary of the Council on Health and Public Instruction, Dr. Frederick R. Green, Illinois, to read the report.

Dr. Green presented the report, which was referred to the Reference Committee on Legislation and Public Relations. (See page 1239.)

Report of Special Committee on Narcotic Drug Situation

The Speaker stated that there was a special committee appointed last year on Narcotic Drug Situation in the United States, and that Dr. E. Eliot Harris, New York, was Chairman of this Committee. He asked Dr. Harris to present the report.

Dr. Harris requested Dr. A. T. McCormack, Kentucky, a member of the Committee, to present the report, which he did, and then the report was referred to the Reference Committee on Legislation and Public Relations.

The report will appear in THE JOURNAL next week.

The House then took a recess until 3 p. m.

Second Meeting—Monday Afternoon, April 26

The House of Delegates reconvened at 3 p. m., and was called to order by the Speaker.

Report of the Council on Medical Education

Dr. N. P. Colwell, Secretary of the Council on Medical Education, in the temporary absence of the Chairman of the Council, Dr. Arthur Dean Bevan, Illinois, presented the report of the Council, which was referred to the Reference Committee on Medical Education. (See page 1243.)

Report of the Council on Scientific Assembly

Dr. J. Shelton Horsley, Virginia, Chairman, presented the report of the Council on Scientific Assembly, which was referred to the Reference Committee on Sections and Section Work, and that part of the report relating to Amendments to the By-Laws was referred to the Reference Committee

on Amendments to the Constitution and By-Laws. (See page 1251.)

Dr. Arthur T. McCormack, Kentucky, moved in behalf of the Committee to strike out the statement of Mr. Eugene Debs in the report of the Special Committee on Narcotic Drug Situation in the United States, and that the report be referred to the Reference Committee on Legislation and Public Relations.

Seconded and carried.

Report of the Committee on Red Cross Medical Work

Dr. Charles W. Richardson, District of Columbia, Chairman, presented the report of the Committee on Red Cross Medical Work, which was referred to the Reference Committee on Reports of Officers. (See page 1251.)

(Insert Ends Here)

New Business

Under the head of "new business," Dr. Randolph Winslow, Maryland, presented the following communication, which was referred to the Reference Committee on Miscellaneous Business:

NEW ORLEANS, April 25, 1920.

At a recent meeting of the Baltimore City Medical Society, a paper entitled "An Argument in Favor of the Establishment of a Medical Newspaper, Comparable to the Trade Journal of Other Walks of Life," was read by Dr. Bertram M. Bernheim.

The Society passed a resolution asking that this paper dealing with the advisability of establishing such a journal be laid before the House of Delegates of the American Medical Association for their consideration.

The Society fully realized the difficulties of carrying out such a project at this time, especially on account of the high cost of printing, but nevertheless felt that it was very essential to give this important matter the most serious consideration at this time, especially on account of the tremendous influence it would have on the education of the people of the United States in health matters.

Mr. Speaker, I move that the Secretary be given authority to distribute this paper to the members of the House and to the various officers of the Association, and that the paper be referred to the proper committee for its consideration and report of that part of the communication dealing with the proposed establishment of a Lay Medical Journal by the American Medical Association.

THOMAS S. CULLEN.

Dr. Edward L. Hunt, New York, offered the following resolution, which was referred to the Reference Committee on Hygiene and Public Health:

Resolved: That the American Medical Association declares its opposition to the Institution of any scheme embodying a system of compulsory contributory insurance against illness, or any other scheme, which provides for medical service to be rendered contributors or others, provided, controlled or regulated by any State or the Federal Government.

Dr. James F. Rooney, New York, offered the following resolution, which was referred to the Reference Committee on Hygiene and Public Health:

Resolved: That the delegates from the State of New York, pursuant to their instructions, desire hereby to express their opposition to any scheme for Compulsory Health Insurance.

Dr. Charles J. Whalen, Illinois, and Dr. F. C. Warnshuis, Michigan, representing their State Delegations, supported the resolution offered by Dr. Rooney.

Dr. Frederic E. Sondern, New York, presented the following, which was referred to the Reference Committee on Hygiene and Public Health:

At the last Annual Meeting of the Surgical Section of the Medical Society of the State of New York, the following resolution was passed:

"It is moved that the Chairman of this Section be empowered to appoint a Committee of Seven from the Medical Society of the State of New York and an honorary committee of seven American Medical Association members (Barker, Cushing, W. Mayo, Longcope, Billings, Tinker, Jones) to review the question of the sale of endocrine products and combinations without a physician's prescription and, if they approve such action to bring the matter to the attention of the American Medical Association House of Delegates for the purpose of further action to prevent the sale of endocrines without a prescription."

WHEREAS: The promiscuous use of the laity of preparations of the glands of internal secretion has led to manifest harm, and

WHEREAS: The uncontrolled use of potent glandular derivatives carries with it the danger of self-medication, be it

Resolved, That the Surgical Section earnestly request that the American Medical Association take the necessary steps to prevent any endocrine preparation being sold to the public except on a physician's prescription. This resolution will be endorsed this afternoon by the Association for the Study of Internal Secretions now in session.

Dr. F. F. Russell, U. S. Army, spoke of the necessity of having published the medical and surgical history of the World War, and stated that the Surgeon-General of the Army had asked Congress to appropriate \$150,000 for this purpose. This history would make approximately fifteen volumes of 600 pages each, and that the edition would be 3,000 copies. He moved that a committee of three be appointed by the Speaker to draft a resolution approving in principle the use of this money by Congress for this purpose.

Seconded and carried.

Ad-Interim Committee

The Secretary presented the following report for the Ad-Interim Committee:

NEW ORLEANS, April 25, 1920.

To the House of Delegates, American Medical Association.

GENTLEMEN:—Speaking for the Ad-Interim Committee, there is one brief matter to report.

About Oct. 1, 1919, a letter was received by the President of the American Medical Association from the Surgeon-General of the Army, containing this paragraph:

"It is requested that you obtain from the members of the American Medical Association, who served in the World War, suggestions with regard to the function and administrative organization of the medical corps of the Army."

To which the President replied: "As President of the American Medical Association, it is my firm conviction that no greater service can be rendered by the profession of this country to the Army, than by giving constructive suggestions for your consideration, tending toward improvement and development of the Army Service."

A meeting of the Ad-Interim Committee was called and was held in Chicago to consider the request of the Surgeon-General. The question was of such importance that the Committee conferred with the Board of Trustees then in session. It was agreed between the Board of Trustees and the Ad-Interim Committee that it would be unwise at that time to proceed without further consultation with the Surgeon-General of the Army. A committee, consisting of the President of the American Medical Association, with Drs. Billings and Simmons, was appointed to confer with Surgeon-General Ireland. A conference was then held with the Surgeon-General, General McCaw and Colonel Russell, in Chicago, on December 1.

At this meeting, it was agreed: First, to request sanction from the House of Delegates that the American Medical Association should assist, in every way possible, in the development of the Walter Reed Medical School, which it is hoped will become the nucleus of a more comprehensive medical center project now in contemplation. Second, that an effort was contemplated to have sanctioned by the medical schools requiring an intern year before a medical degree in the Walter Reed or other Army hospitals as hospitals in which students could serve as interns and be duly credited for a degree by such service. Third, it was further agreed that when Congress should pass the Army Reorganization Plan, the finding on what basis the Medical Corps and Medical Reserve Officers should act, then the Surgeon-General would submit for constructive suggestions a plan of reorganization of the Medical Corps and Medical Reserve Corps to a Committee of Medical Reserve and Regular Officers having had experience at home and abroad in the recent war. Until such time as these preliminaries are accomplished, there appears to be no further action necessary to be taken by the Committee of the American Medical Association as appointed by the Ad-Interim Committee.

It is therefore recommended that the House of Delegates confirm the action of this subcommittee acting for the Ad-Interim Committee.

Dr. A. T. McCormack, Kentucky, moved that the action of the Ad-Interim Committee be approved.

Seconded and carried.

Dr. H. B. Gibby, Pennsylvania, Chairman, presented a supplementary report for the Committee on Credentials, stating that 107 delegates had been so far seated.

It was moved and seconded that the report be accepted.

Carried.

The Speaker appointed the following committee to prepare suitable resolutions asking Congress to publish as soon as possible the medical and surgical history of the War: Dr. Gerald B. Webb, Colorado; Dr. Walter R. Steiner, Connecticut, and Dr. Leroy Crummer, Nebraska.

Dr. John D. McLean, Pennsylvania, stated that a resolution was introduced last year in the House of Delegates urging that the publications issued by the Surgeon-General of the Army during the War be placed in such a position as to be available to the medical profession, but that he could not find any record of the resolution.

Dr. Frank Billings, Illinois, stated that this resolution was referred to the Board of Trustees. After conference with the Surgeon-General of the Army, other officers, and the Librarian, the Board of Trustees found there were no available books for distribution to the medical profession. He further stated that the supply of books published by the Army Medical Department and offered for free distribution had been exhausted.

On motion, which was duly seconded and carried, the House of Delegates adjourned to meet at 9:30 a. m., Tuesday, April 27, 1920.

(To be continued)

Causes of Death in U. S. Registration Area.—The Census Bureau's annual compilation of mortality statistics for the death registration area in continental United States shows 1,068,932 deaths as having occurred in that area in 1917, representing a rate of 14.2 per 1,000 of population. Of these deaths, nearly one third were due to three causes—heart diseases, pneumonia and tuberculosis—and nearly another third resulted from the following nine causes: Bright's disease and nephritis, apoplexy, cancer, diarrhea and enteritis, arterial diseases, influenza, diabetes, diphtheria and bronchitis. The deaths from heart diseases (organic diseases of the heart and endocarditis) numbered 115,337, or 153.2 per hundred thousand population. Pneumonia (including bronchopneumonia) was responsible for 112,821 deaths, or 149.8 per hundred thousand. Tuberculosis in its various forms caused 110,285 deaths, of which 97,047 were due to tuberculosis of the lungs. The death rate from all forms of tuberculosis was 146.4 per hundred thousand, and from tuberculosis of the lungs, 128.9. Bright's disease and acute nephritis caused 80,912 deaths, or 107.4 per hundred thousand. Apoplexy was the cause of 62,431 deaths, or 82.9 per hundred thousand. Cancer and other malignant tumors caused 61,431 deaths, of which number 23,413, or 38 per cent., resulted from cancer of the stomach and liver. The rate from cancer has risen from 63 per hundred thousand in 1900 to 81.6 in 1917. Diarrhea and enteritis caused 59,504 deaths, or 79 per hundred thousand. Arterial diseases of various kinds, atheroma, aneurysm, etc., resulted in 19,055 deaths, or 25.3 per hundred thousand. Influenza was responsible for 12,974 deaths, or 17.2 per hundred thousand. Deaths from diabetes numbered 12,750, or 16.9 per hundred thousand. Bronchitis caused 12,311 deaths, or 16.3 per hundred thousand. Typhoid fever resulted in 10,113 deaths, or 13.4 per hundred thousand. Measles, whooping cough and scarlet fever were together responsible for 21,723 deaths of both adults and children, or 28.8 per hundred thousand. The rates for the three diseases separately were 14.3, 10.4 and 4.2, respectively. Deaths due to external causes of all kinds—accidental, suicidal and homicidal—numbered 81,953 in 1917, corresponding to a rate of 108.8 per hundred thousand population.—*Pub. Health Rep.* 34:1474 (July 4) 1919.

POISON IVY, OAK AND SUMAC

There are many perennially recurring menaces to health which the physician is never allowed to overlook or forget, because the advent of afflicted patients serves as a potent reminder. If the cause of danger is an avertible one, like the fourth-of-July fireworks or the human contamination of water supplies bringing about a high morbidity rate for typhoid fever, it is well worth while to keep preaching the necessity of prevention. The campaigns of warning and education carried on annually by THE JOURNAL in relation to the two life-threatening features just cited, for example, have finally resulted in greatly reducing the harm done by eradicating the causes or at least reducing their frequency. At this season the publicity columns are likely, and with good reason, to direct attention to the impending menace of the mosquito and the undesirability of the fly.

The summer season is likewise the period when poisonous plants flourish and exert their noxious effects. Hence it is timely to send out the usual warnings about ivy and sumac poisoning.¹ The species of *Rhus* which are responsible for it infest virtually all parts of the country, except mountain elevations above about 6,000 feet and arid lands. They are not infrequently found growing along city streets, in parks and on private property as well as in the fields, pastures and woodlands of the country. Consequently there is scarcely a physician who has not encountered cases of intoxication from these poisonous plants. Indeed, medical experience testifies to the widespread discomfort and even serious illness which annually result.

It is generally agreed that the active principle common to the poison oak, ivy and sumac is toxicodendrol, an acid resin (not an oil, as stated in *Public Health Reports*). As little as 0.001 mg. is said to be sufficient to produce vesication of the skin. This remarkable potency must be kept in mind in attempting to explain the readiness of injury and the ease with which the poison "spreads" on the skin. Several commonly

quoted peculiarities of ivy poison need to be critically considered. One of these is the belief that persons of suitable susceptibility may become poisoned without any contact whatever with the harmful plants. One frequently hears the statement that the mere observation or passing of the plants may be followed by intoxications. As toxicodendrol is nonvolatile, such alleged occurrences, often reported from apparently authentic sources, need careful consideration. The government experts have reached the conclusion that probably many cases supposed to have originated through the transfer of some volatile emanation have actually been due to direct or indirect contact. The exact manner in which the poisoning has occurred may readily be overlooked, since in many instances the appearance of the eruption is delayed for several days, and traces of the poison sufficient to produce injury may be conveyed by clothing or other articles long after contact with the plants. Sweet and Grant¹ add that numerous attempts to produce poisoning experimentally by emanations from *Rhus* plants, and from the active principle itself, have been unsuccessful. On the other hand, there is excellent foundation for the popular belief that smoke from the burning plants will give rise to irritation, and some of the worst cases of *Rhus* poisoning undoubtedly originate in this manner. Another tradition concerns the alleged immunity of certain persons. Here, too, careful investigation tends to indicate that this is at best one of degree, and that complete insusceptibility of man has neither been demonstrated nor induced.

In considering a rational treatment, it should be known that the irritant substance is soluble in alkalis, in gasoline and in alcohol, but is precipitated by lead acetate. At one time lead washes formed a popular treatment for ivy poisoning. They accomplish at best the precipitation of the poison in situ. It must then be removed in some way to avert further danger; and many persons are susceptible to intoxication by lead as well as by ivy poison. The widely advocated scrubbing with soap and hot water is efficacious only so far as it mechanically removes the toxicodendrol before it penetrates the skin. To spread the toxic agent inadvertently by washing rather than to remove it can only aggravate the danger. This applies particularly in the case of commonly used alcoholic lotions; their use must be thorough and liberal lest they merely serve to dissolve the poison and hence distribute it. The treatment with hot alkaline solutions of potassium permanganate is not as widely recognized as it merits to be. The principle involved consists in the destruction of the poison by this oxidative agent. The discoloration of the skin by the reagent can readily be removed by lemon juice or other means.

The physician has in this connection a larger function than the mere diagnosis and relief of ivy poisoning. He ought to lead in an effective crusade to destroy the

1. A timely paper on this subject has been published by the U. S. Public Health Service (Sweet, E. A., and Grant, C. V.: Ivy and Sumac Poisoning, *Pub. Health Rep.* 35:443 [Feb. 27] 1920) from which various statements have been taken.

noxious vegetation, which flourishes in most unsuspected places. A campaign of popular education in the nature of the dangers involved as well as in the recognition of the harmful plant forms should be started every year. Communities should be waked up to the importance of eradicating the persistently growing poison ivy. It is surely not too much to expect that a few seasons of persistence fostered by medical sanction will decrease one of the causes of a "seasonal torment" that need not be with us.

DOES HEMATOGENOUS JAUNDICE OCCUR?

The occurrence of jaundice as a symptom of conditions in which there is an obstruction of the bile ducts either outside of the liver or within the hepatic tissue has long been readily understood. In contrast with this obstructive or mechanical jaundice, there has been considerable discussion in recent years regarding the possibility of a nonobstructive type, referred to commonly as hemolytic jaundice. For the genesis of this it has been assumed that hemoglobin, the assumed precursor of the bile pigments, is somehow liberated in abnormal quantities in the circulation. From this free blood pigment bilirubin is supposed to be formed apart from any participation of the liver, in which the conversion normally takes place. Such considerations have therefore led to the differentiation of the usual "hepatogenous" jaundice from the less common "hematogenous" jaundice in which, no disorder of the liver or biliary ducts being apparent, the bile pigments were supposed to be found in the blood vessels or elsewhere in consequence of the destruction of erythrocytes and the conversion into bilirubin of the blood pigment thus liberated.

In order to establish the independent identity of the so-called hematogenous or nonobstructive jaundice, it is necessary to be able to exclude all conditions which might involve obstruction to the usual flow of bile at any point in its course from the liver cells. Among the facts offered in evidence for the existence of the nonhepatic jaundice has been the failure to find either macroscopic or microscopic indications of interference with secretion when necropsies in supposed cases have been performed. Furthermore, it is pointed out that in the alleged hematogenous jaundice the stools are normally colored, so that no lack of a discharge of bile into the bowel, such as occurs in biliary obstruction, can be assumed. Again, it is pointed out that a tendency to anemia associated with a susceptibility of the red blood corpuscles to hemolysis often constitutes the appropriate accompaniment of the jaundice symptoms. Finally, the removal of the spleen, an organ which has frequently been held responsible for the hemolytic phenomena, is said to abolish the jaundice of hematogenous origin; in the latter event the liver and its ducts can scarcely be assumed to play any part.

Without reviewing further the varied arguments that have been advanced in support of the occurrence of a jaundice independent of any liver factors, it should be understood that such statements have not been allowed to go unchallenged. The classic objection is found in the well-known experiments of Minkowski and Naunyn demonstrating, for some species at least, that although extensive hemolysis accompanied by icterus can be induced by means of certain poisons, jaundice does not ensue if the liver has been previously removed. Again, it has repeatedly been pointed out that in cases of assumed hematogenous jaundice, the existence of minute obstructions of the bile passages and the occurrence of hepatic lesions discoverable only by careful histologic study undoubtedly occur.

Naunyn,¹ to whom we owe many important contributions to the knowledge of jaundice, in lately reviewing his extensive experience, has remarked that in considering so-called hemolytic jaundice in individual cases, all too little attention has been paid to the possible existence of obstruction factors. Thus, he asserts that there is no convincing evidence whether bile salts are actually absent or present in the icteric urine. The presence of these compounds would at once point to a hepatogenous origin of the jaundice. Naunyn, who is convinced that the liver plays a part in all cases, regards hemolytic jaundice as the outcome of an infectious disease in which a cholangitis frequently is the conspicuous feature. The harmful agent, whatever it may happen to be, is believed to find its way to the liver as a rule from intestinal sources. The implication is that if more careful studies of the liver could be made at suitable times, hepatic damage sufficient to produce partial obstruction would be detected. In other words, icterus invariably means implication of the liver.

Gerhart² also has recently come to a similar conclusion. He points out that at times the stools of patients suffering from hemolytic jaundice are actually decolorized, or the pigments may be diminished. Hence, careful repeated observations may disclose symptoms of bile obstruction when they are unsuspected. The determination of the degree of obstruction, i. e., the complete or incomplete freedom of bile flow, is not easy, so that the argument of color in the feces must be used with caution by advocates of either side of the controversy. Gerhart likewise intimates the difficulty of excluding minute obstructive changes in the liver—alterations too small for obvious notice, yet sufficient to produce some reabsorption of bile in localized areas. He has also cited cases in which relief gained from extirpation of the spleen was only temporary, in harmony with the fact that the fundamental liver factors are by no means excluded through

this surgical procedure. Finally, numerous cases of hemolysis in which jaundice never occurs can be cited.

Before abandoning the theory of an independent hematogenous jaundice, it must be recalled, however, that Whipple and his associates in San Francisco have reported experimental evidence of the occurrence of bile pigments in the urine after injection of hemoglobin into dogs with the liver excluded from the circulation. What value is to be assigned to these observations in the face of the current tendency to reemphasize the significance of the liver in most, if not all, forms of jaundice remains to be seen.

ALIMENTARY PROTECTION AGAINST HEMOLYTIC STREPTOCOCCI

Hemolytic streptococci have deservedly acquired the reputation of being dangerous invaders of the human organism. The menace which they represent has been aggravated of late by the repeatedly verified observations that these types of micro-organisms are frequently harbored not only by the sick, but also by normal persons. For this reason the unsuspected dissemination of the streptococci becomes a serious possibility. Cultural studies made in various army camps during the war gave indisputable evidence of the large extent to which the hemolytic streptococci are found in the throat and tonsils.¹ As an illustration, we may cite Smillie's² observation that about 50 per cent. of normal throats harbor these bacteria; the assertion of Blanton, Burhans and Hunter³ that hemolytic streptococci could be obtained from the tonsils of normal persons in 90 per cent. and from the depths of the tonsils in 80 per cent. of their cases; and likewise the observations of Pilot and Davis,⁴ showing that in the crypts of the faucial tonsils hemolytic streptococci occur in nearly 100 per cent. Such facts have been brought to bear on the question of the efficacy of complete tonsillectomy as a procedure for the elimination of a breeding place for hemolytic streptococci.

From the foregoing circumstances it becomes evident that large numbers of streptococci must be constantly passing beyond the pharynx into the alimentary canal. Furthermore, the same dangerous types can reach the gastro-enteric tract through the medium of food. What becomes of them? Are they readily destroyed by some protective mechanism in this part of the body, or do they continue to thrive and furnish an added menace by reappearing in the stools ready for further dissemination in sewage? These questions

have recently been put to a test by Davis,⁵ who examined the feces in fifty-three cases without finding hemolytic streptococci. They were absent even from the feces of scarlet fever patients, who almost always have these micro-organisms in their throats in very large numbers.⁶

As hemolytic streptococci are not ordinarily found in appreciable numbers in the gastro-intestinal tract of rabbits, though these animals are especially susceptible to experimental infection with *Streptococcus hemolyticus*, Davis introduced large amounts of virulent cultures of the organisms into the stomach of this species. Occasionally the bacteria pass through the canal under these exceptionally severe conditions and appear in the feces. As a rule, they do not thrive or gain a permanent foothold there. Rabbits with generalized streptococcus infection in the joints and blood showed no hemolytic streptococci in the intestinal contents.

One naturally inquires how this alimentary protection is acquired. Davis has referred it to the gastric secretion. Juice of normal acidity from man kills hemolytic streptococci within five minutes, though the gastric secretion in achylia may not kill them in several hours. This is only a new added instance emphasizing the enormous advantage of proper acidity in the stomach in controlling the alimentary flora. In the fecal mixture at body temperature, *Streptococcus hemolyticus* likewise does not seem to thrive long. Such facts may serve to exonerate this type of streptococci from primary responsibility for some of the manifestations of enteritis which were charged to it before the modern sharp differentiations could be made. Whether or not hemolytic streptococci play a significant part in the production of pathologic lesions of the bowel, under conditions in which the defenses against the microbial invaders fail, remains to be more carefully investigated.

Current Comment

THE TREATMENT OF ATROPHY IN DENERVATED MUSCLES

When the nerve supply to a peripheral muscle is interfered with, atrophic changes in the latter are likely to follow. The atrophy, until recently, has usually been ascribed to the inactivity supposed to follow the loss of innervation. The routine treatment has therefore been of a character expected to counteract the disuse of the contractile tissue. Electric stimulation, massage, passive movements, hydrotherapy and other mechanical procedures have been employed to avert muscular atrophy, particularly when there seems to be a chance for a regeneration of the nervous connections if all the tissues concerned are kept in good physiologic con-

dition. The Cambridge physiologist Langley¹ suggested four years ago, however, that muscular atrophy in a denervated muscle is due, not to inactivity, but to continuous fibrillation. A connection between atrophy and fibrillation has long been recognized; thus, Barker² wrote in 1910: "Where the degenerative atrophy is due to lesion of the anterior horns or of the motor nuclei of the cerebral nerves, fibrillary twitching is commonly present." The relations of cause and effect are not clearly indicated here. If the disuse theory is to be abandoned, there seems to be no rational basis for the employment of therapeutic measures intended to promote the circulation and thus retain the nutrition and functional capacity of the muscles involved. Actual experimentation on animals with denervated muscles has, indeed, shown the futility of electrical stimulation and massage. As a denervated muscle is not a muscle at rest, the only indication of possible success in treatment thus far found has been in ionization with salts to stop the twitching.³ The report recently published in *THE JOURNAL* by Hartman and Blatz⁴ is a further record of inability to demonstrate benefit from either galvanic stimulation or massage. As was to be anticipated, the fibrillation was not checked. Although it may not be a welcome necessity to throw the current treatment of such muscular atrophy into the discard, particularly when no promising substitute procedures are suggested, a frank recognition of the truth alone can lead to progress.

CHOLIN IN THE BODY

Cholin is a nitrogenous base which can be obtained as a derivative of the phosphatid lecithin by mild decomposition. Cholin is not devoid of physiologic potency, though it can scarcely be regarded as a pronouncedly toxic substance. Some closely related compounds, notably neurin and muscarin, are far more potent. A few years ago it was widely believed that cholin might arise from disintegration of lecithin in the nervous tissues, in which the lipoid is abundant, or elsewhere in the body, and might exhibit toxic effects. These were assumed, for example, to manifest themselves in certain types of nerve degeneration and in the cell destruction following application of roentgen rays. There is reason to believe now that many of the earlier reports of the presence of cholin in blood and tissue fluids rest on inaccurate procedures of analysis. Reid Hunt,⁵ who devised a physiologic test that permits detection of as little as 0.00001 mg. of cholin, was unable to obtain evidence that this substance is of any significance in either physiologic or pathologic processes. A corroboration is further afforded by the studies of Guggenheim and Löffler⁶ at Basel. They estimate that a liter of blood serum contains, from 0.002 to 0.02 gm.; the same quantity of urine contains

about the same proportion of cholin. In several diseases investigated, no characteristic variations in the content of cholin in the body fluids could be observed.

BOTULISM DUE TO OLIVES

The continued occurrence of fatal outbreaks of botulism poisoning caused by contaminated olives prompts our frequent reference to this situation. Many of the features of botulism outbreaks are still quite obscure; and in view of the urgent necessity for practical methods of prevention, every contribution to our knowledge of this form of food poisoning should be closely considered by sanitarians and health officials. The summary of the investigations of the Bureau of Chemistry on olive poisoning, given elsewhere in this issue,¹ contains material of general interest and practical application. Four of the five outbreaks reported in the summary were due to a toxin produced by the Type A of *Bacillus botulinus*; the organism responsible for the fifth attack is not yet differentiated. Type A is the type found in California, and differs from the type present in the Eastern states and apparently from that observed in Europe. The summary leaves one in some uncertainty as to whether green olives as well as ripe olives have been implicated in botulinus poisoning. In the Montana outbreak, olives stuffed with pimiento are considered to have been the source of the trouble, and in another instance "olive relish" in a tin container was the substance involved. It is not clear whether the "relish" was made of green or ripe olives, but it is certainly true that green and not ripe olives are commonly used for "stuffing." The title of the Bureau of Chemistry summary, on the other hand, seems to limit the poisoning to ripe olives, so that a clear statement on this point seems desirable. The important question as to whether or not *B. botulinus* contamination in canned food is always accompanied by physical signs of decomposition seems to be answered in the affirmative by the experience of the government investigators. They state that in all of the material examined by them in which *B. botulinus* was present, the odor was distinctly offensive. This characteristic is a doubtful safeguard, however, since olives washed, iced or served with highly flavored foods may not betray their dangerous nature, particularly to persons unfamiliar with the natural taste of ripe olives. The source of the odor does not seem to be cleared up by these investigations. Whether the disagreeable smells are due to the products of *B. botulinus*, or whether the other micro-organisms apparently always present in the imperfectly sterilized contents of the jar or can have given rise to the putrefactive conditions, is left undetermined by the evidence printed in the article cited. The conclusions of the Bureau of Chemistry workers that more efficient methods of sterilization should be employed, that brine packing should be modified, and that olives should be handled with the same degree of care and cleanliness as any other perishable food product seem abundantly justified.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Personal.—Dr. Frank W. McCorkle, Huntsville, has resigned as assistant health officer of Madison County to become county health commissioner of Decatur County, Ga. Dr. Roscoe C. Stewart, Huntsville, has been selected as Dr. McCorkle's successor.

Bacteriologic Society Organized.—The Birmingham Bacteriological Society, with a charter membership of fourteen, was organized by laboratory experts and physicians at Birmingham, March 17. Dr. A. H. Olive was elected president; Miss Blanche Frazier, vice president, and Dr. James R. Bean, secretary-treasurer.

CONNECTICUT

Personal.—Dr. Walter H. Brown, health officer of Bridgeport, has been appointed associate director, department of health service, national headquarters, American Red Cross. —Dr. John W. Churchman, New Haven, professor of surgery in Yale University, has been named Officier de l'Académie with silver palms in recognition of work done as chief of the medical service of Military Hospital No. 32 bis, during 1916. —Dr. William B. Terhune, New Haven, has been appointed director of the division of mental hygiene of the state board of health.

ILLINOIS

Chicago

Personal.—Dr. William R. Cubbins has been appointed chief of the surgical staff of Cook County Hospital; Dr. Joseph A. Capps, chief of the medical staff; Dr. Channing W. Barrett, chief of the gynecologic staff; Dr. Edwin R. LeCount has been placed in charge of the pathologic laboratories and Dr. Julius Hess of the department of diseases of children. —Dr. Daniel H. Williams has been honored by the University of Pennsylvania by having his name given to a special organization among the medical students, known as the Daniel H. Williams Surgical and Oral Society. The prime object of the organization is to encourage research work.

Teaching Health to Children.—A child health school for the training of teachers of health to children will be held this summer at the University of Chicago. There will be a group of underweight children to serve as a demonstration of methods of conducting nutrition classes and teaching general health habits. Assistant Prof. Lydia J. Roberts of the department of home economics, who has recently returned to the university after making a nutrition survey of children for the U. S. Children's Bureau, will be the director, and Dr. Mendenhall of the Children's Bureau and Dr. Walter H. O. Hoffmann of Rush Medical School will serve as medical advisers.

INDIANA

Nurses' Home at City Hospital.—The city board of health of Indianapolis has decided to start action to provide a bond issue for the construction of a nurses' home at the City Hospital. The undesirability of the living quarters has made it difficult for the hospital to keep up its required staff of nurses.

Personal.—Dr. James B. Young, Cumberland, has been appointed associate medical director of the Indianapolis Life Insurance Company, succeeding Dr. Mitchell A. Devaney, deceased. —Dr. Charles C. Crampton, Delphi, has been elected commander of the local post of the American Legion.

Postgraduate Course.—The Indiana University School of Medicine will give a postgraduate course in disease production and immunity in its department of pathology, beginning June 1, 1920. The course will cover a period of six weeks of lectures and laboratory work.

IOWA

Clinic at Grinnell.—A free clinic for children needing medical or surgical attention has been established at St. Francis' Hospital, Grinnell.

Personal.—Dr. Jefferson D. Blything has been appointed city physician of Davenport on recommendation of the Medical Society of Davenport. —Dr. James W. Richards has been appointed health physician of LeClaire. —Dr. Alphonse L. Hageboeck, Davenport, was elected commodore of the Davenport Boat Club, April 5. —Dr. Charles L. Barewald has been elected mayor of Davenport. —Dr. Don M. Griswold, Iowa City, has accepted the chair of public health and hygiene in the Medical School of the University of Iowa, and by this acceptance becomes state epidemiologist.

MARYLAND

Personal.—Dr. William H. Welch, for thirty-five years pathologist of Johns Hopkins Medical School and now director of the School of Hygiene and Public Health, celebrated his seventieth birthday anniversary, April 8. —Dr. Winifred Cullis, professor of physiology in the London School of Medicine for Women, University of London, and chairman of the Committee on International Relations of the University Women of Great Britain, spoke in Baltimore at the College Club recently both to the students of Goucher College and to the College Women of Baltimore.

University of Maryland Enlarged.—A bill recently passed by the Maryland legislature combines the Maryland State College of Agriculture with the University of Maryland School of Medicine under the name of the University of Maryland. The new institution now possesses, therefore, a college of arts and sciences, a military school and schools of medicine, dentistry and pharmacy. A new board of nine trustees has also been established. The legislature also appropriated \$42,500, each year, for the medical school for the next two years and in addition appropriated \$185,476.85 for the other departments of the university for the year 1921, and \$165,416.89 for the year 1922. Another appropriation of \$203,000 was made for buildings and equipment. This adds one more to the list of states having state universities, the total now being twenty-nine.

MICHIGAN

Clinic Opened.—A clinic for the treatment of crippled and deformed persons has been opened in Detroit under the auspices of the local board of health. The expenses are being paid by the Sigma Gamma fraternity, and members of that organization are serving as attendants. Drs. Carroll L. Storey and Nathaniel Ginsberg are in charge of the clinic.

The Carstens Semicentennial.—Members of the Wayne County Medical Society gave a testimonial dinner, April 13, in honor of Dr. J. Henry Carstens, Detroit, who has just completed his fiftieth year as a practitioner of medicine. Dr. George E. McKean, president of the Wayne County Medical Association, officiated as toastmaster, and speeches touching on different phases of Dr. Carstens' life were made by Drs. Daniel La Ferte, Theodore A. McGraw, Guy L. Kiefer, Preston M. Hickey, Angus McLean, John N. Bell and H. Wellington Yates.

MINNESOTA

Personal.—Dr. Leroy E. Doolittle has been appointed school physician of Duluth. —Dr. Archibald L. McDonald, Duluth, has been elected president of the St. Louis County Medical Association and Dr. Herbert G. Lampson, secretary.

Health Work in State.—Following out an idea which originated when Dr. Walter R. Ramsey, St. Paul, suggested that the children's specialists of the state organize and bring their advice to the inhabitants of the counties rather than to restrict expert diagnosis of the children's cases to people living in the larger cities, twenty-four specialists on diseases of children, ten dentists, fourteen medical directors of tuberculosis sanatoriums, many eye and ear experts, the Minnesota Obstetrical and Gynecological Society and a trained dietitian have formed an advisory staff for the Minnesota Public Health Association and have conducted health clinics in almost every county of the state during the last year.

NEW YORK

Poster Contest Time Limit Extended.—The time limit of the contest started by the bureau of venereal diseases of the state department of health in which a prize of \$100 was offered for the best poster illustrating the quotation "Healthy Parents Head Happy Families," and which was noted in THE JOURNAL of March 13, has been extended from May 1 to June 1.

Clean-Up Week.—In a letter to mayors, village presidents and boards of health, Dr. Hermann M. Biggs, state commissioner of health, has designated the week beginning April 26 as the annual clean-up week. The commissioner emphasizes the necessity of impressing the citizens of each community with the date and purpose of clean-up week in order that the large amount of filth and rubbish which has accumulated during the winter may be collected and properly disposed of. Local authorities are urged to make adequate provision for the prompt removal and destruction of all such material. The suggestion is made that a local committee composed of representatives of various organizations be formed in each community for the purpose of supervising the work.

New York City

Jacobi Memorial.—The New York Academy of Medicine will hold a memorial meeting in honor of Dr. Abraham Jacobi's ninetieth birthday anniversary, May 6, at 8:30 p. m. A bas-relief of Dr. Jacobi will be presented by George McAneny and will be accepted by the president of the academy, Dr. George David Stewart. The principal address will be delivered by Dr. George E. Vincent of the Rockefeller Foundation.

New Quarantine Regulations.—Amendments to the sanitary code provide the following minimum periods of quarantine: diphtheria, twelve days from onset, after which until two cultures taken not less than twenty-four hours apart, preferably from both nose and throat, fail to show the presence of diphtheria bacilli; scarlet fever, thirty days after onset, providing discharges from nose and ears have ceased; cerebrospinal meningitis, fourteen days from onset; acute anterior poliomyelitis, three weeks from onset; typhoid fever, until ten days after the patient's temperature reaches normal, and further until two specimens of feces collected after an interval of at least twenty-four hours are found to be free from typhoid bacilli.

PENNSYLVANIA

Institutions Closed.—The Emergency Hospital, Erie, established to meet the scarlet fever epidemic, closed for the reception of patients, April 3, and will definitely close the end of this month.—State Health Department Dispensary No. 11, Chambersburg, established by the late Dr. H. X. Bonbrake, was discontinued, March 26.

Personal.—Dr. James F. Trimble, Greensburg, has been appointed medical director of Westmoreland County.—Dr. Fred Wade Paton, Bradford, medical director of McKean County, has resigned.—Dr. Isaac H. Shelly, Jr., Amhler, has been appointed a member of the eye, ear, nose and throat staff of the Montgomery County Hospital and also consultant at the Norristown State Hospital.

New Officers.—At the annual meeting of the board of directors of the Pennsylvania Society for the Prevention of Tuberculosis held in Philadelphia, April 14, Dr. James M. Anders, Philadelphia, was elected president of the board of directors, succeeding Dr. Thomas McCrae, Philadelphia; Drs. Joseph S. Neff, William D. Robinson, Philadelphia, and Dr. William C. White, Pittsburgh, were elected vice presidents; Dr. Ware Brinton, Philadelphia, was made secretary; J. William Hart, treasurer, and Drs. Elmer H. Funk, Philadelphia, and Thomas McCrae, Philadelphia, were elected members of the board.

State Police to Aid in Fighting Disease.—Important cooperative work between the state police force and the state department of health in the campaign for eradication of social diseases has been arranged and hereafter when state policemen make arrests in raids, medical officers will accompany them and conduct examinations. If necessary, state policemen will assist the health authorities in maintenance of a quarantine against persons found suffering from infectious diseases. The details of the cooperative plan were worked out by Major Lynn G. Adams, the superintendent, following an address to the troop officers by Dr. Sigmond L. Gans of the department of health, who outlined the procedure under the act of 1919. State police work in the bureaus of fire protection and criminal identification will be materially expanded this year.

Philadelphia

Appropriation for Insane.—An ordinance to appropriate \$50,000 to improve conditions of the insane at the Philadelphia General Hospital and to create thirty-eight important positions was approved by council's health committee, April

22, and referred with a favorable recommendation to the finance committee. The new system established would range from a medical director at \$5,000 a year to two hydrotherapists at \$900 a year each, requiring an appropriation of \$35,373 annually. The ordinance would also appropriate \$14,000 for alterations necessary for the introduction of new methods of treatment of patients at the institution.

Personal.—Drs. John Welsh Croskey and Lawrence Webster Fox have been elected censors of the Philadelphia County Medical Society to fill the vacancies caused by the resignations of Dr. Jay Frank Schamberg and Dr. Judson Deland.—Dr. John Blair Spencer, physician in chief of the department of public welfare, returns this week from Washington, D. C., where he went about ten days ago to submit to an operation necessitated by an injury received while serving in the Navy during the late war.—Dr. Andrew A. Cairns, chief of the city health bureau, has been appointed a member of the advisory board of the department of health to succeed Dr. Joseph S. Neff, former director of health and charities, who resigned.—Dr. Miriam Warner has been appointed physician to the women patients of the Holmesburg Institutions, including the Home for the Indigent and Brown's Farms.—Dr. Randle C. Rosenberger has resigned as director of the pathologic laboratories at the Philadelphia General Hospital.

SOUTH CAROLINA

Personal.—Dr. T. B. Brown, Charleston, has taken charge of the Anderson Clinic, succeeding Dr. L. W. Blake, resigned.—Dr. Reuben G. Hamilton, Rockton, has been elected head of the public health service of Fairfield County, with headquarters at Winnsboro.

Increased Appropriation.—The Medical College of the State of South Carolina has received an appropriation from the state of \$71,000 for maintenance, as compared with \$49,500, the previous appropriation. An additional appropriation of \$60,000 was made for the physiology building and equipment.

Medical Bill Now Law.—Governor Cooper on March 10 signed the medical bill, requiring all chiropractors, osteopaths, homeopaths and other healers to submit to examination before the state board of medical examiners.—The state board of medical examiners held a meeting, April 19, at Greenville, to formulate the new rules for the examination and licensure of practitioners, and the first examination will be held on June 22.

To Study Trachoma.—Drs. Edward F. Parker, Charleston; Charles W. Kollock, Charleston; Edwin R. Wilson, Sumter; Pinkney V. Mikell, Columbia; E. Mikell Whaley, Columbia; Martin Crook, Spartanburg, and Waller H. Nardin, Anderson, have been appointed by Dr. James A. Hayne, Columbia, state health officer, as a committee to investigate trachoma and other infectious diseases of the eye, and to formulate rules and regulations to prevent the spread of these diseases among schoolchildren.

New State Officers.—The South Carolina Medical Association, at its seventy-second annual meeting, held in Greenville, S. C., April 20 and 21, elected the following officers: president, Dr. Washington P. Timmerman, Batesburg; vice presidents, Drs. Miles J. Walker, York; William A. Boyd, Columbia, and William W. Fennell, Rock Hill; secretary-treasurer, Dr. Edgar A. Hines, Seneca, and councilors, Drs. Archibald E. Baker, Charleston; Samuel E. Harmon, Columbia; Thomas L. W. Bailey, Clinton; Leland O. Mauldin, Greenville; T. N. Duten, York; Charles R. May, Bennettsville; Harry L. Shaw, Sumter, and Leighton A. Hartzog, Olar.

VIRGINIA

To Fight Swamp Menace.—The health committee of Newport News has made recommendation that the council appropriate an emergency fund of \$5,000 to defray the expenses of the fight against the malaria menace in the swamps and marshes in the city.

Institute for Colored Physicians.—By the aid of the missionary fund of the National Tuberculosis Association, the colored physicians of Virginia have been given a course of lectures and clinic work in tuberculosis at the Piedmont Sanatorium, Burkeville. The instructors comprise the heads of the three tuberculosis sanatoriums of Virginia and the medical director of the state tuberculosis association. Patients of all stages of tuberculosis were examined and the practitioners were drilled in the technic of chest examinations. The course will be repeated in June.

Health Center for Norfolk.—The public health department of Norfolk, through its director, Dr. Powhatan S. Schenck, has for several years been developing plans for a public health center for the city. A large amount of money has been secured for the work and plans for the buildings have been prepared. The proposed site for the buildings is the court house block at Bank Street. In the middle of the group will be the old Academy building which will be remodeled to contain the children's court, domestic relations court and other enterprises connected with these courts. On the sides and to the front of this will be grouped the general medical building, the prenatal building, the detention building, and administration and emergency buildings. The latter will be equipped so that it may be used for accident, operation and emergency cases. The general medical building will be fully equipped to treat all diseases except contagious diseases.

CANADA

Mental Hygiene Course.—The social service department of the University of Toronto is completing enrolment in the special extension course in mental hygiene. About thirty-five will take lectures in this course which will be conducted daily until June 11. Applications have come from Hamilton, Ottawa and other parts of the province of Ontario.

Harvey Club Election.—At the annual meeting of the Harvey Club, London, Ont., the following officers were elected: honorary president, Dr. Clarence M. Crawford, Whitby; president, Dr. Francis W. Hughes, London; vice president, Dr. John I. Ferguson, London; secretary, Dr. James W. Crane, London (reelected), and treasurer, Dr. Uriah E. Bateson, London.

Venereal Disease Council.—At the meeting of the Ontario committee of the Canadian Council for Venereal Diseases held, March 5, in Toronto, the lieutenant-governor was elected honorary president; Dr. Charles A. Hodgetts, Ottawa, president; Dr. Storms and Mrs. Torrington, Toronto, were elected vice presidents; Dr. Robert R. McClellanham, Hamilton, was elected secretary, and M. L. Wood, treasurer.

Six-Year Medical Course.—Recently a conference was held in Montreal at which were present representatives of the medical department of the University of Toronto and the University of McGill. The delegation representing the University of Toronto included Profs. John J. Mackenzie, Benjamin P. Watson, Duncan A. L. Graham, Velyien E. Henderson, Drs. Edward Stanley Ryerson and Alexander Primrose, C. B. No final decisions were reached at that conference, but there was a preliminary discussion of the curriculum to be adopted by both institutions from the first to the sixth year. Both Toronto and McGill had decided to introduce the six-year course before the war.

Canadian National Council for Combating Venereal Diseases.—The first municipal committee in connection with the above organization has been organized in Toronto with Hon. Mr. Justice Riddell as honorary chairman; Dr. Frederick W. Marlow, chairman, and Dr. Gordon A. Bates, secretary. Coincident with the organization of this committee, there was shown in Massey Hall, Toronto, the film drama "The End of the Road." About 17,000 viewed this moving picture, and at the same time addresses were delivered of an educational character. The first work of the national council committee will consist in general education among the people to prove to them the seriousness of the problem of venereal diseases. Government treatment schemes will be inaugurated in various parts of the dominion. An endeavor will be made to secure a large membership.

Tuberculosis Board for Military Hospitals.—A board of tuberculosis sanatorium consultants has recently been appointed by the director of military services of the Soldiers' Civil Re-Establishment. The personnel of this board is as follows: Drs. Charles D. Parfitt, Gravenhurst; John R. Byers, Ste. Agathe des Monts; William M. Hart, Qu'Appelle, Sask.; Arthur F. Miller, Kentville, N. S., and David A. Stewart, Ninette, Man. This board will visit the twenty-three sanatoriums throughout Canada in which patients of the department are receiving treatment. The board will study the whole situation in Canada with regard to the treatment of tuberculosis occurring among soldiers, and as far as possible will bring about uniform standards of treatment, equipment, records, etc. The medical superintendents of these sanatoriums have been instructed to cooperate in every way with the board.

Personal.—Surg.-Gen. John T. Fotheringham left Toronto, March 18, for a trip to the West Indies.—Dr. Gerald Allison, Picton, Ont., has returned after serving with the R. A.

M. C. in Turkey.—Dr. Russell J. Collins, Kentville, N. S., has been appointed medical superintendent of the Balfour Sanatorium, Balfour, B. C.—Dr. William H. G. Aspland, Toronto, who was with the British Red Cross Society in 1914, is now living in Yorkshire, England.—Dr. Richard D. Cowan, Toronto, after three years of war work, has engaged in graduate work in the Middlesex Hospital, London, England.—Dr. Helen MacMurchy, Toronto, has been appointed head of child welfare under the department of public health, Ottawa.—Dr. Thomas J. McNally, Guelph, who has been district medical officer of health for the counties of Grey, Bruce and Simcoe, Ont., has been transferred to the Sarnia district.—Dr. George L. Sparks, London, after returning from overseas a short time ago, was appointed district medical officer of health for Fort William, Ont.

GENERAL

Tri-State Physicians Meet.—The forty-seventh semiannual meeting of the Northern Tri-State Medical Association of Indiana, Ohio and Michigan was held in Goshen, Ind., April 8, in connection with the annual session and as the guest of the Elkhart County Medical Association.

International Opium Convention.—Under terms of the Versailles Treaty of Peace and the Covenant of the League of Nations, all signatory nations are under obligation to ratify the opium convention and to enact the necessary legislation for its enforcement within twelve months. General supervision over the execution of the convention is entrusted to the League of Nations.

Post-Graduate Hospital Endowment Fund.—The New York Post-Graduate Medical School and Hospital reports that a total of \$751,694 has been reached in its \$2,000,000 endowment fund campaign. Among the large contributors were: Mrs. James Farrell, \$25,000; Mrs. Stephen Olin, \$500; J. M. W. Hicks, \$500; Mrs. Vanderbilt, \$500; F. W. Jennings, \$500; Hornblower, Miller, Garrison and Potter, \$500; Anonymous, \$5,000; Henry J. Davis, \$500; Fred Huyler, \$500; Warner B. Leeds, \$500, and Artemus Ward, \$1,000. An anonymous contribution of \$20,000 has also been received.

Military Surgeons Hold Meeting.—At the annual meeting of the Association of Military Surgeons of the United States held in New Orleans, April 22 to 24, under the presidency of Col. Joseph A. Hall, M. C., Ohio N. G., Cincinnati, the following officers were elected: president, Asst. Surg.-Gen. John W. Kerr, U. S. P. H. S., Washington, D. C.; vice presidents, Med. Dir. (Captain) Frank M. Pleadwell, M. C., U. S. Navy, Washington, D. C.; Col. Charles Lynch, M. C., U. S. Army, Washington, D. C., and Col. David S. Fairchild, Jr., M. C., Iowa N. G., Clinton, Iowa, and secretary-treasurer and editor, Col. James Robb Church, M. C., U. S. Army, Washington, D. C. (reelected). The 1921 meeting will be held in Washington, D. C., probably in October.

Bequests and Donations.—The following bequests and donations have recently been announced:

Paterson, N. J., General Hospital; St. Joseph's Hospital, and Barnert Hospital, each \$5,000; Paterson Orthopedic Association and Paterson Eye and Ear Infirmary, each \$4,000, by the will of William H. Heap, Paterson.

Paterson, N. J., General Hospital; St. Joseph's Hospital, and Barnert Hospital, each \$5,000, by the will of Lewis Levi, Paterson.

Woman's and St. Luke's hospitals, New York City, each \$5,000; Society of Widows and Orphans of Medical Men of New York City, \$1,000, by the will of Mrs. Anna M. Sandham.

Children's Hospital, Philadelphia, \$1,000, and after the death of one relative \$10,000, by the will of Mrs. Francis A. Roberts.

Philadelphia Home for Incurables and Philadelphia Home for Consumptives, each \$1,000, by the will of Catherine A. Delk.

New York Post-Graduate Medical School and Hospital Endowment Fund, \$250,000, contingent on the raising of \$1,000,000, by James F. Brady and Vincent Astor.

FOREIGN

Personal.—The Copenhagen University has awarded the Salomonsen prize to Prof. V. Ellermann for his works on leukemia in fowls. The fund for promotion of research on diabetes has been awarded to Dr. H. C. Hagedorn.—Prof. Vittorio Maragliano, son of Senator and Professor Maragliano of Genoa, has had two fingers amputated on account of roentgen injury in his professional work as radiologist.—Prof. K. Landsteiner of Vienna has accepted a call to the Hague as chief of the public hospital, and has resigned his post as director of the institute for pathology at the Wilhelminenspital a Vienna.

Nicolai and the Berlin Medical Students.—THE JOURNAL mentioned Jan. 26, 1918, that Prof. G. F. Nicolai on his return to Germany had been imprisoned for publishing a

book, "The Biology of War," in which he pointed out the warping of the conceptions of German scientists and military men in the course of hostilities, disregarding humanity and citing specific instances. Nicolai escaped by aeroplane to a neutral country, but returned later and was recently appointed professor extraordinary by the minister of public instruction, K. Haensch. When he opened his course of lectures, the students created such a disturbance, denouncing him as a traitor, that he has been unable to continue the course. The governing board of the University of Berlin has also recently formally declared that he is unworthy of a chair in the university "as he had forsaken the country and his civilian duties and had published in a neutral country a book which placed poisoned weapons in the hands of the foe." The *Deutsche medizinische Wochenschrift* comments that "members of all parties must agree in this judgment, and the grounds therefor. It is remarkable, however, that the university authorities did not protest in this way at the time Nicolai was given the chair last October." Before the war he was privat-docent of physiology.

Deaths in Other Countries

Dr. M. T. Buch of Helsingfors, author of manuals "Physiology of Appetite and Hunger," "Physiology of Digestion" and smaller works along these lines, aged 70.—Dr. Norberto Barbot of Montevideo, formerly chief of the public health service in the state of Rio Negro and for many years the leading physician of Fray Bentos, aged 57.—Dr. Oriol Solé Rodríguez, the minister representing Uruguay at Lima, Peru, aged 60. He had been a member of the Uruguayan parliament and minister from Uruguay at Hamburg, and later in Italy and Brazil until appointed minister plenipotentiary to Peru, aged 60.—Dr. Isidro Lobo, formerly inspector general of the medical department of the Argentine army with which he had been connected since 1883.—Dr. A. Steiger, a well known ophthalmologist of Zurich.—Dr. R. Archambault, medical inspector of the port of Rosario, Argentina.—Dr. V. Ferreira dos Santos, who occupied a high position in the medical department of the army of Portugal.

LATIN AMERICA

Scientific Board in Nicaragua.—In accordance with the recommendation of the superior board of public health, the government has established a scientific board for the eradication of yellow fever. The board will have charge of all matters relative to yellow fever cases and the prevention of the disease. Telegraph, telephone and postal frank privileges have been granted to this body.

New Sanitary Convention Between Brazil, Uruguay and Argentina.—Uruguay has taken the lead in the effort to unify sanitary requirements in regard to third class passengers arriving at their ports. The president and public health service of Uruguay ask that each of the countries will appoint a delegate to confer and adopt a uniform plan of requirements with which the navigation companies will have to comply.

Tribute to Two Men of Science.—Under this heading the *Crónica Médica* of Lima, Peru, publishes an official notice from the president of the republic to the effect that as it is the duty of the public powers to present to the gratitude of the people and of posterity the memory of men who by their knowledge and character have contributed to national progress, he has ordered that statues of the two physicians, Dr. H. Unánue and Dr. B. Herrera, be erected in the university park at Lima at the expense of the state.

Dismissal of Dr. Ribeyro.—Dr. Ramón Ribeyro, director of the National Institute of Vaccine of Peru, has just been dismissed from his position by the director of public health. In his letter commenting on this matter, Dr. Ribeyro recalls that he had occupied this position for twenty-four years and had just been appointed corresponding member of the Society of Exotic Pathology of Paris because of his work on tropical diseases.

Academy of Medicine Offers Prize.—The Academy of Medicine of Porto Rico offers its fifth annual prize for the best work on "A Practical and Economic Plan for Rural Sanitation in Porto Rico." The prize amounts to \$500. The contest is open only to physicians located in Porto Rico, and the articles must be typewritten, make no mention of the author's name (this should be given in a separate closed envelop, having the same motto as the original article), and be in the hands of the secretary of the academy, Dr. P. Gutiérrez Igaravidez, San Juan, on or before Sept. 15, 1920.

Government Services

Health Conditions of the Army

During the week ending April 16, there was a slight increase in the hospital admission and death rates, but a decrease in the number of new cases of communicable diseases. Measles is reported in numbers from several stations, but nowhere has it assumed epidemic proportions. Of fifteen deaths from disease, eight were caused by tuberculosis, and two by pneumonia. Eight new cases of influenza, five of pneumonia, three of scarlatina, two of diphtheria and three of varicella are reported from the American Expeditionary Forces in Germany.

Public Health Service Hospitals

Up to date, twenty-one army hospitals have been turned over to the Public Health Service by the War Department. No others are now available, and the Committee on Public Buildings and Grounds will be called on to appropriate at least \$15,000,000 for the purchase and construction of additional hospital units to take care of immediate requirements for ex-service men under the War Risk Insurance Act. In the Urgent Deficiency Bill, just approved by the House Committee on Appropriations, \$7,666,000 is placed at the disposal of the Public Health Service for its fiscal requirements to June 30, 1920.

Army Reorganization Bill

The Army Reorganization Bill has passed both the Senate and House, but because of some differences it will be submitted to a conference committee. The House bill fixes the entrance age limit of an Army medical officer at 54 years; the Senate bill at 50 years. The former provides for the promotion of medical officers according to length of service by a board of from three to five officers, subject to review by the Secretary of War; the Senate bill provides promotion to the grade of captain after three years' service, to major after fourteen years, to lieutenant-colonel after twenty years and to colonel after twenty-six years. Both bills provide that medical officers who were in service during the World War and are now in the Medical Reserve Corps will be eligible for appointment in the regular Army after July 1, 1920. Commissioned rank for nurses is prescribed in both bills.

Foreign Letters

LONDON

April 10, 1920.

Military Control of the Army Medical Department

In the House of Commons, Lieutenant-Colonel Fremantle delivered a powerful criticism of army medical administration. He pointed out that the director-general of the army medical service was responsible only for the provision of physicians, nurses, drugs, instruments and dressings. When a breakdown occurred it was almost invariably in the provision of hospitals, or equipment, or in transport arrangements. The tragic breakdowns in the Crimean and South African wars were due to the difficulty of coordination. The result was the hospitals commission, which recommended that the director-general of the army medical service should be on what was then called the army board; but all that was arranged was that he should be summoned to the army council whenever his advice and special knowledge were required. But who knew when the advice of the specialist was required? Expeditions were undertaken without consulting him. The report of the Dardanelles commission showed that the errors were due largely to the lack of cooperation and provision in thinking out the probabilities. A committee of investigation recommended that the director-general of the army medical

services should come under the adjutant-general, because sanitation was so much a question of discipline. It was; but hospitals depended on other things that came from the quartermaster-general, from military intelligence and from the chief of the general staff, and there was no reason why hospitals or other branches of the medical service should come under any one of those three officers. An officer was needed on the army council who would be responsible for all materials and supplies, and who would have the power required to get hospitals efficient. Lord Esher, who presided over the committee referred to, had said: "How much the suffering undergone by our soldiers in the war was due to the shortsightedness of my committee will never be known." Certainly, the control of the adjutant-general's branch of the army medical corps was and is responsible, not only for the early failure to grip the medical factors of this war, but for the hampering conditions under which Sir Alfred Keogh worked. His triumphs and those of the army medical corps were achieved in spite of obstacles that the subordination of science to ignorance, of elasticity to military discipline, explains but cannot justify. Lieutenant-Colonel Fremantle appealed to the government to strengthen the army council by placing on it the director-general of medical services and to free from the control of a purely military officer a body of men mostly volunteers from highly trained professions and dealing with technical difficulties altogether outside the orbit of vision in which the soldier pure and simple habitually moved. Mr. Churchill, secretary of state for war, complimented Lieutenant-Colonel Fremantle on his speech, and promised that it would be carefully studied and examined by those in the war office specially concerned with the subjects mentioned.

An Appeal for Medical Journals from Austria

In the *Times*, Sir Clifford Allbutt makes an appeal on behalf of Austrian physicians and students. He has heard from Professor Wenckebach that their penury is so great that they cannot afford a cent for books or journals, home or foreign. He therefore appeals to Great Britain for recent medical and scientific literature for which students in all faculties are athirst. He describes the zest with which a group of students will pounce on any fragment of a journal which may drift into their bare libraries. Sir Clifford Allbutt therefore begs the readers of the *Times* not to throw away journals, books or papers, and perhaps to make some little sacrifice to spare such literature for the Vienna University. A London firm has undertaken to forward them in bulk.

The Rationing of Butter and Sugar in the Case of Invalids

The only foods now rationed are butter and sugar. The maximum amount of government butter which food committees can grant is 4 ounces weekly in ordinary cases and 8 ounces in cases of tuberculosis, diabetes and cancer. Applications for extra butter must be accompanied by a certificate that failure to obtain the extra ration would either (a) be definitely prejudicial to the health of the applicant or (b) delay his recovery. A certificate to the effect that the applicant is unable to digest margarin will no longer be required in view of the difficulty experienced by physicians in giving such certificates. In making this concession, the ministry impresses on physicians that there is still a serious shortage in supplies of imported butter, and asks for their cooperation in limiting such applications to cases in which they are fully satisfied that, owing to exceptional circumstances, margarin will not meet the needs of the patient. Extra allowances of sugar may be granted up to 1 pound weekly (inclusive of the ordinary ration) to applicants unable to take solid food, either on account of difficulty in swallowing or because their

disease necessitates a "slop" diet, and up to 10 ounces weekly (inclusive of the ordinary ration) to children under 2. Food control committees will not themselves deal with, but will forward to the medical section of the ministry applications for extra sugar in the cases of: (a) elderly persons who by reason of infirmity are on a specially limited diet; (b) delicate children who are unable to eat much solid food or whose parents are, through lack of means, unable to provide substitutes for sugar, and (c) tuberculous patients whose diet is certified by the physician to be limited either by reason of poverty or because of the disease's being in an acute stage, and when a larger allowance is recommended than the committee itself is empowered to grant.

A National Institute of Psychology and Physiology as Applied to Industry and Commerce

An appeal for the foundation of such an institute has been made with the support of leaders of industry; psychologists and physiologists, like Dr. C. S. Meyer of Cambridge, Prof. C. S. Sherrington, and Prof. E. H. Starling; and educationists such as Sir Robert Blair and Sir Alfred Keogh. Of the means proposed, one of the chief is the establishment of a well-equipped laboratory or laboratories for research into various occupations, in order to determine the conditions necessary to get maximum output with minimum of fatigue and discomfort to the worker, such as elimination of unnecessary movements; and to study the causes of mental and muscular fatigue and the methods of reducing it. Tests would be made in the laboratory for the purpose of establishing standards by which workers can be selected for the occupations for which they are best suited, mentally and physically. These standards would enable parents and after-care committees to be advised as to the best vocations for children, and would thus eliminate much waste at the outset, and prevent the discontent which arises when a worker finds out too late that he has taken up an unsuitable occupation and is a square peg in a round hole. The facts established by research would be collected and classified, and from time to time published in such a form as to bring out their practical value. Another function of the institute would be to provide training courses and lectures for investigators, managers, foremen and welfare workers in the practical applications of psychology and physiology, and it would undertake investigations at factories and offices in relation to any special problem. It would study the conditions that tend to promote the health, comfort and welfare of the worker, and also the psychologic relations between employer, manager, foreman and worker, with special reference to securing harmony and cooperation. It would further undertake propaganda work among employers and employed, and cooperate actively with organizations of both, for the furtherance of national unity and prosperity.

The Measurement of Emotion

At the Royal Society of Medicine, Prof. A. D. Waller, F.R.S., gave a very interesting lecture on the measurement of human emotion. He pointed out that emotion produced appreciable changes in the skin, such as vasomotor effects and sweating. He believed that there existed other phenomena under the control of the central nervous system. Cell metabolism was probably influenced directly by impulses arising in the central nervous system. Under certain influences the porous envelops surrounding every cell became more porous, and cell metabolism increased; under others, they became less porous, and cell metabolism diminished. These changes could be appreciated by the alterations produced in the resistance to the electric current. The hand of a subject was placed in the arm of a Wheatstone bridge and the resistance measured. A painful stimulus, physical or psychic, then caused a deflection of the mirror galvanometer. He thought that the alteration of

resistance was due to nervous impulses passing down the peripheral nerves and acting on the cells through their surrounding membranes. In the passive state, resistance varied in different individuals and at different times of the day. There was a definite daily cycle in resistance, which was highest during the early hours of the morning and lowest in the afternoon. These periods corresponded with the periods of minimum and maximum metabolism. For these observations the palms or soles should be used; with other surfaces of the body the reactions were less marked and were open to doubt. The reason for this was obscure. A practical demonstration was then given on an assistant and a volunteer from the audience. The striking of a match with the threat of burning caused an immediate deflection of the galvanometer. The actual burning caused a greater diminution. A deflection occurred when the subject coughed. This was due, not to any emotion associated with the cough, but to the passage of a nervous impulse down the nerves of the arm. There was an interval between the cough and the deflection of the galvanometer, which was attributed to changes at the periphery rather than in the highest centers. Contrary to expectation, hysterical subjects proved less likely to show deflection than normal persons.

Leprosy as a Deficiency Disease

The fish hypothesis of leprosy was advocated with his characteristic persistency by Sir Jonathan Hutchinson throughout his long life. The incredulity with which it was received did not disturb him in the least. The greatest observer of his age, if indeed not of any age, he read the book of nature with infinite care and the insight of genius. Like all reformers, he had encountered incredulity and opposition in his greatest advances. If here they were more lasting, the only thing to do was to go on teaching. He maintained that leprosy was due to eating fish in a state of incipient decomposition. The cause was "some ingredient or parasite generated by or introduced into fish which had not been cured or cured badly." A study of the geographic distribution convinced him that neither climate nor race had anything to do with the disease. The observation that it prevailed almost exclusively on islands, on the shores of continents, and along the courses of rivers led to the conviction that it must in some way be due to the eating of fish. He accumulated an immense amount of evidence, such as the following: Leprosy is more prevalent among Roman Catholics than among those by whom fish is not eaten by reason of religious ordinance. The Jains and high-caste Brahmans of India, who are strict vegetarians, are almost free from leprosy. Leprosy did not affect the Hottentots until smoked fish was introduced among them. The number of lepers in the whole of India is five in 10,000, while in the fishing island of Minicoy it is 150 in 10,000. All over the world leprosy is a disease of the tribes that fish and not of those that hunt. Of these and kindred facts adduced by him and too numerous to mention, no other explanation than his has ever been given. But the discovery of the bacillus of leprosy by Hansen in 1874 caused a revival of the contagionist doctrine of leprosy, and it was assumed that a disease due to a specific bacillus could not be due to any article of food. And so the position has remained. But at the Royal Society of Medicine a paper has just been read by Mr. A. S. Dutton which tends to show that after all Hutchinson was right—as he always was—in the conclusion which he drew from the facts, though not in his pathologic speculation. He could not have arrived at the truth in this, for the conception of "deficiency diseases" did not then exist. Mr. Dutton referred to Hutchinson's observation that leprosy never developed in the United States except in parts of California, which he attributed to the fact that it was almost the only country where colonization took

place without an initial stage of considerable hardship, and that a good variety of foods was practically always available. Mr. Dutton remarked that though leprosy was considered to be due to *B. leprae*, it was curious how closely the nervous symptoms of beriberi resembled those of lepra anaesthetica. Each was also prevalent in the far East. Lepra anaesthetica could occur without lepra tuberculosa and be present for a considerable time before the latter. This appeared to support the food theory. Mr. Dutton suggested that when the food supply was mainly fish, a deficiency in diet occurred. The salting of fish would produce a loss in its nutritive value. Leprosy might eventually be recognized as partly a deficiency disease, sometimes owing to a predisposition caused by a diet mainly of fish, and sometimes to a diet deficient in various necessary elements. If the bacillus then gained access to the body, the whole chain of tuberculous manifestations would be added.

Miners' Nystagmus

It is fairly well known with what great activity the industries of the Liège basin have combated occupational diseases in general. The hookworm dispensaries for miners obtained appreciable results, and in this preventive campaign, Professor Malvoz succeeded in eradicating a disease that had become a great menace. A rather curious disease observed in the mines, and against which serious measures are being taken, is miners' nystagmus. In reality, among all miners who work under bad lighting conditions, in metal mines as well as coal mines, visual fatigue is common. The fatigue may be limited to the photoreceptor structures of the eye (causing hemeralopia and defective retinal perception), but most often it passes this stage and attacks the centers that govern muscular equilibrium and the protective reflexes of the eye, causing nystagmus and blepharospasm. It results in visual disorders which become progressively worse, and which lead finally, especially among coal miners, to psychic disorders from exhaustion of the central nervous system (amblyopia, tics and neuroses). The latter eventuality is fortunately rare; ordinarily the troubles are limited to the visual apparatus. The manifestations are extremely variable in different subjects, and even in the same subject at different times. The clinical evolution of this fatigue depends on the physical condition of the individual person and on his physiologic resistance. There are periods of aggravation and remission. The symptoms are aggravated by enfeebling intercurrent diseases, such as pneumonia and typhoid fever. Workmen who are poorly nourished, weakened by overwork or privation, and those with domestic difficulties are easy prey for serious forms of the disease. Good physical condition, and proper rest and nourishment, on the contrary, act as deterrents to the development of the disease. Dr. Stassen has just published a statistical and experimental work on the subject. Of almost 20,000 miners examined by him, about 5,000, or 25 per cent., presented signs of varying degree of ocular fatigue. In the metal mines, only the benign and occasionally the moderately intense forms were found. In coal mines, however, all degrees of ocular fatigue were encountered. Of 1,000 coal miners, eighty had slight visual fatigue at the end of the day, 125 had some slight nystagmus, thirty had a marked diminution of vision with nystagmus, ten were partly incapacitated for work, and two had ocular neurosis and general nervous disorders which made them totally incapacitated for work. Dr. Stassen says that improved lighting of the mines is the first requisite in the prevention of visual disorders among miners. He cites cases of severe ocular fatigue which disappeared after the men

worked in pits with galleries lighted by incandescent electric lamps or in metal mines lighted by acetylene lamps. A successful campaign against miners' nystagmus requires the cooperation of the public authorities, mine owners and miners, a cooperation based on the same principles as the campaign against hookworm disease among miners in Liège province.

Abdominal Hysterectomy

Dr. Frans Daels presented an interesting paper on the indications and technic of total abdominal hysterectomy before the Académie royale de médecine. He insists on hysterectomy in the treatment of cancer of the cervix. After a careful bacteriologic study of the parametrium, he has reached the conclusion that the streptococcus infection which exists in the carcinomatous area in 60 per cent. of the cases extends besides, six times out of ten, to the parametrium and to the lymphatic glands. The preliminary treatment before operation on patients with infection consists in curettage and cauterization of the base of the cancerous crater, followed by applications of radium for fifteen days. This preventive treatment permits better clearing away of the carcinomatous lesion and improves the general condition, but it does not inhibit the infection or prevent the infected tissues from coming in direct contact with the peritoneum, the ligatures and the suture lines. Therefore, the author wonders if it is not possible to disinfect these tissues, or, at the very least, to stop the extension of the infection. Clinical and laboratory experience justify him in recommending a solution of silver nitrate, 1 per cent. in a 0.5 per cent. solution of nitric acid, as having a direct bactericidal action and as stimulating proliferation. This topical treatment does not prevent Dr. Daels from considering careful peritonization of the true pelvis as the best preventive of extension of the autochthonous infection. In two of his cases the surfaces were successfully covered with large transplants from the peritoneum. After the hysterectomy is done, the walls of the vagina are fixed to a band formed by suturing the round ligaments together. This assures the organs of the true pelvis their normal plastic and static surroundings.

Lethargic Encephalitis

Lethargic encephalitis has made its appearance in Belgium. In western Europe the disease first appeared at Verdun in 1915, and at Bar-le-Duc in 1916. It was first clearly recognized in Paris and London in March, 1918, and numerous papers have appeared on the subject in France and England. In the latter country, the government organized a scientific investigation; the report of this commission concludes that lethargic encephalitis is a clearly defined disease. The first paper on the subject in the Belgian medical press was that by Drs. Burger and Focquet. At a recent meeting of the Académie royale de médecine, Dr. Paul Masoin reported several cases of the disease, and recalled some cases which appeared in Flanders a year ago, especially at Ruddervoorde, where it assumed epidemic proportions. These cases were the subject of a report by Professor Van Ermengem to the Conseil supérieur d'hygiène in October, 1919. The disease was restricted to a few villages of Flanders for one year, but is now distributed over all provinces. For this reason, Dr. Masoin proposed that the academy recommend that the department of hygiene direct the attention of the medical profession to the disease and request all physicians to report suspected cases to health inspectors and to note any peculiarities which might help in studying the disease. Up to the present no attention has been paid to this appeal, except in one instance, the report by Drs. Lamalle and Leroy of the apparition of the disease in Liège. Their case was observed during a small epidemic of influenza.

Deaths

Cassius M. Witmer ☉ Santa Ana, Calif.; Jefferson Medical College, 1881; aged 61; for thirty-five years a practitioner of Marble Hill, Mo.; formerly a member of the board of managers of the State Hospital, Farmington, Mo.; president of the Bollinger County Bank, Lutesville, Mo.; director of the Bank of Marble Hill, Mo., and of the South East Missouri Trust Company, Cape Girardeau, Mo.; vice president of the Telephone Company at Advance, Mo.; died, April 11, from cerebral hemorrhage.

Bernard Bartow ☉ Buffalo; University of Buffalo, 1874; aged 70; a member of the American Orthopedic Association and American Academy of Medicine; orthopedic surgeon to the Children's Hospital and consulting orthopedic surgeon to the Central and Municipal hospitals, Buffalo; emeritus professor of orthopedic surgery in his alma mater; died in the Children's Hospital, Buffalo, March 29.

William Henderson Ruddick, Boston; Harvard University Medical School, 1868; aged 75; a member of the Massachusetts Medical Society; assistant surgeon of the Seventh Massachusetts Infantry during the Civil War; also a veteran of the war with Spain; formerly assistant superintendent of the New Hampshire State Hospital, Concord; died, April 8.

Buford Nelson Dunavant ☉ Memphis, Tenn.; Memphis (Tenn.) Hospital Medical College, 1906; aged 37; major, M. C., U. S. Army, and attached to the 115th Field Artillery; formerly major, M. C., N. G., Tenn., and assigned First Infantry; was shot and fatally wounded by policemen summoned to quiet a disturbance at his residence, April 11.

Peter Winslar Franklin Corning, Londonderry, N. H.; Baltimore Medical College, 1906; aged 47; a member of the New Hampshire Medical Society; while driving in his automobile over a grade crossing south of Londonderry, April 12, was struck by a train, and died while being taken to the Lawrence (Mass.) General Hospital.

Seth Wicks ☉ Chicago; University of Illinois, Chicago, 1903; aged 40; captain, M. R. C., U. S. Army, with service at Camp Custer, Mich., and discharged Jan. 29, 1919; instructor in biology in his alma mater; died in Lake View Hospital, Chicago, April 24, after an operation for appendicitis.

Edward Joseph Connell ☉ New York City; Cornell University Medical College, New York City, 1899; aged 43; assistant ologist to the Lincoln Hospital, and assistant ophthalmologist and aural surgeon at the Fordham University Dispensary, New York City; died, April 11, from pneumonia.

Henry Sherman Kilby, North Attleboro, Mass.; Harvard University Medical School, 1878; aged 68; a member of the Massachusetts Medical Society; for many years school physician and a member of the school committee of North Attleboro; died, April 10.

Mead Charles Carpenter ☉ Linesville, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1895; aged 55; while driving in his automobile over a grade crossing of the Pennsylvania system at Linesville, April 9, was struck by a train and instantly killed.

Kire Le Clare Clock, Ravenwood, Colo.; Barnes Medical College, St. Louis, 1899; aged 56; physician of the Victor-American Mine; died, April 22, from the effects of poison, self-administered, it is believed, with suicidal intent.

Isaac Irwin Kalbach, Glen Riddle, Pa.; Jefferson Medical College, 1893; aged 48; a member of the Medical Society of the State of Pennsylvania; died in the Taylor Hospital, Ridley Park, Pa., April 16, from cerebral hemorrhage.

Robert Lee Taylor, Cleveland, Tenn.; University of Nashville, Tenn., 1897; aged 50; died in his office, April 7, from the effects of a gunshot wound of the head, self-inflicted, it is believed, with suicidal intent, while despondent.

Walter Ross, The Pas, Man.; Manitoba Medical College, Winnipeg, 1909; aged 33; Major, Canadian A. M. C. and D. A. D. M. S.; died in the Canadian Hospital, Buxton, England, February 6, from pneumonia.

Martin Friedrich ☉ Cleveland; Western Reserve University, Cleveland, 1894; aged 63; chief of the Bureau of Communicable Diseases of Cleveland; for many years health officer of the city; died, April 8.

Henry Oliver Conoway, Grand Island, Neb.; Eclectic Medical Institute, Cincinnati, 1875; aged 71; formerly of Phillips, Neb.; died in the Grand Island General Hospital, April 1, from cerebral hemorrhage.

☉ Indicates "Fellow" of the American Medical Association.

Earl E. Craig, Wilson, Ark.; University of Tennessee, Nashville, 1907; aged 41; a member of the Arkansas Medical Society; was killed by the overturning of his automobile in Wilson, March 30.

Arthur O. Sax ☉ Chicago; Hahnemann Medical College, Chicago, 1897; aged 52; professor of theory and practice of medicine in his alma mater; died, April 23, from valvular heart disease.

Charles Ernest Walters, Dexter, Mo.; Barnes Medical College, St. Louis, 1907; aged 41; captain, M. C., U. S. Army; a member of the Missouri State Medical Association; died, March 26.

Percy Bissell Grant, Roblin, Manit.; Manitoba Medical College, Winnipeg, 1908; aged 39; died in the Winnipeg General Hospital, January 5, from appendicitis.

John Trumbull, Vina del Mar, Chile, S. A.; Harvard University Medical School, 1880; aged 64; died in Valparaiso, Chile, February 26, from chronic endocarditis.

Iverson L. Lofton, Nashville, Tenn.; University of Nashville, Tenn., 1860; aged 79; a Confederate veteran; died, March 20, from cerebral hemorrhage.

Victor H. Parker, Carmi, Ill.; Jefferson Medical College, 1876; aged 67; died in a hospital in Jacksonville, Fla., April 6, from cardiorenal disease.

Joseph Johnston Shanks, Salem, Va.; University of the City of New York, 1882; aged 63; died at McAlpin, W. Va., March 31, from pneumonia.

John J. Theorell, Porter, Ind.; Hahnemann Medical College, Chicago, 1898; aged 71; died, February 20, from chronic interstitial nephritis.

Thomas John Nolson Gatrell, Santa Ana, Calif.; Rush Medical College, 1900; formerly of Oberlin, Ohio; died, February 12.

Valentine Bowers, Frankfort, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1880; aged 77; died, March 4.

Julius Jerome Go'dstein, New York City; University and Bellevue Hospital Medical College, 1909; aged 33; died, April 14.

William James Weeks, Ottawa, Ont.; Queen's University, Kingston, Ont., 1865; aged 80; died, February 22, from heart disease.

A. Thomas Buchanan, Chicago; St. Louis Medical College, 1872; aged 78; a veteran of the Civil War; died, April 22.

Reuben T. Giffin, Burnett's Creek, Ind.; Fort Wayne (Ind.) College of Medicine, 1892; aged 75; died, March 3.

H. Burton Kirkland, Berea, Ohio; Eclectic Medical Institute, Cincinnati, 1891; aged 52; died, April 21.

Franz G. Koehler, Philadelphia; aged 92; a practitioner since 1849; died, March 8, from pleurisy.

James Case Brixey, Chicago; College of Physicians and Surgeons, Chicago, 1905; died, April 22.

Robert Reid Weir, Itasca, Texas; University of Nashville, Tenn., 1884; aged 62; died recently.

Simon D. Hornocker, Silverville, Ind. (license, Indiana, 1897); aged 87; died, March 16.

Marriages

CHAUNCEY DEWITT BEEBE, Sparta, Wis., to Miss Marguerite Dreeneen Bittner of New York City, at Chicago, April 3.

HAROLD KOCH SHAWAN, Detroit, to Miss Jane Coleman, at Chicago, April 19.

CHARLES ALLEN MCWILLIAMS to Miss Nona Harry, both of Gulfport, Miss., April 8.

WARREN ASHLEY COLEMAN to Miss Christine Edwards, both of Eastman, Ga., May 1.

JAMES HOWARD HUDDLESON, JR., to Miss Mary Ellen Pascoe, both of New York City, February 17.

JOSEPH G. WILSON to Miss Anne Dunning, both of New York City, April 19.

HENRY WILLIAM ABELMANN to Miss Anabel Borg, both of Chicago, April 17.

FREDERICK HOLTON MORRISON, Newton, N. J., to Miss Mary C. Shaw of Stanhope, N. J., March 24.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

SOME MISBRANDED DRUG PRODUCTS AND NOSTRUMS

Quinin Sulphate and Calomel Tablets.—The Drug Products Company, New York City, shipped in September, 1917, quantities of "Quinin Sulphate Tablets" and "Calomel Tablets" which were adulterated and misbranded. The tablets of quinin sulphate were labeled as 2 grain tablets. Analysis by the Bureau of Chemistry showed that they actually contained only about 1½ grains (1.54 gr.) of quinin sulphate to each tablet. The calomel tablets were labeled as ¼ grain, while the Bureau of Chemistry's analysis showed that they actually contained less than ¼ grain (0.156 gr.) calomel to each tablet. In December, 1918, the company pleaded guilty and was fined \$20.—[Notice of Judgment No. 6636; issued March 22, 1920.]

Some Miscellaneous Tablets.—The Carroll Dunham Smith Pharmacal Co. of New York City shipped in September, 1917, a number of tablets which were declared adulterated and misbranded. Some "Acetanilid Tablets" which were labeled as 5 grains were found to contain only 2.98 grains, or a shortage of 40 per cent. Some "Nitroglycerin Tablets" which were labeled as ½ grain were found to contain only 0.0139 grain, or a shortage of 30 per cent. Some "Acetylsalicylic Tablets" labeled as 5 grains were found to contain only 4¼ grains, or a shortage of 15 per cent. Some "Acetphenetidin and Salol Tablets" labeled as containing 2½ grains each of acetphenetidin and salol were found to contain only 0.37 grains acetphenetidin and 1.45 grains of salol per tablet, being a shortage of 85 per cent. and 42 per cent., respectively. Some "Quinin Sulphate Tablets" which were labeled 2 grains were found to contain approximately 1.3 grains, or a shortage of 33 per cent. In December, 1918, the company pleaded guilty and was fined \$25.—[Notice of Judgment No. 6682; issued March 29, 1920.]

Hostelley's Hypophosphites.—William H. Hostelley, who traded as W. H. Hostelley & Co., Philadelphia, shipped in November, 1917, some "Hostelley's Hypophosphites (Syr. Hypophos. Comp.)" and also "Hostelley's Chemically Pure Hypophosphites (Sol. Hypophos. Comp.)" which were adulterated and misbranded. These products were adulterated because when analyzed by the Bureau of Chemistry they were found to vary widely both from their declared composition and also from the National Formulary requirements. The "Syr. Hypophos. Comp." was also declared misbranded because it was falsely and fraudulently represented as a cure for tuberculous manifestations, neurasthenia, rickets, anemia, bronchial affections, nervous insomnia and senile depression "when in truth and in fact it was not." The "Sol. Hypophos. Comp." was also declared misbranded because it was falsely and fraudulently represented as a cure for tuberculous manifestations, alcoholic or sexual neurasthenia, all nervous and mental diseases, physical depression, senile decay and anemia when it was not. In February, 1919, Hostelley pleaded guilty and was fined \$100 and costs.—[Notice of Judgment No. 6747; issued April 9, 1920.]

Stoddard's Pinus-Codeia and Miscellaneous Tablets.—G. S. Stoddard & Co., New York City, in November, 1917, shipped "Stoddard's Pinus-Codeia" and various tablets which were misbranded. The "Pinus-Codeia" was misbranded in that it failed to bear a statement of the quantity or proportion of codeia contained in each fluidounce of the article and it also failed to state that codeia is a derivative of opium. Some "Salcetol-Codeia Tablets" were misbranded in that

while they contained acetanilid, the amount of this drug was not declared on the label; neither did the label carry the information that codein sulphate is a derivative of opium. "Salcetol Phenylamine Ammonii Salicylate Tablets" was falsely and misleadingly labeled in that it was represented that the tablets contained ammonium salicylate when they did not and for the further reason that while the tablets did contain acetanilid the quantity or proportion of acetanilid was not declared. "Salcetol Co. No. 2 Infant Corrective" was sold under the claim that it contained bismuth subnitrate, zinc sulphocarbolate and phenylacetamide when as a matter of fact it contained none of them. It was further misbranded in that the label declared that it contained $\frac{1}{30}$ of a grain calomel and no sugar when, as a matter of fact, it contained more than $\frac{1}{30}$ of a grain of calomel and did contain sugar. "Cannabin Co. Tablets" were labeled as containing $\frac{1}{40}$ gr. strychnin phosphid and $\frac{1}{400}$ gr. brucin to each tablet; as a matter of fact they contained only about $\frac{1}{77}$ gr. of strychnin phosphid and no brucin. In February, 1919, the company pleaded guilty and was fined \$70.—[*Notice of Judgment No. 6714; issued April 9, 1920.*]

Dr. King's Star Crown Brand Pills.—The Northern Drug Co., Duluth, Minn., shipped a quantity of this stuff in August, 1917. The federal chemists reported that these pills consisted essentially of aloes and oil of pennyroyal and were coated with chalk, charcoal and sugar. The preparation was falsely and fraudulently represented as a cure for delayed and painful menstruation and menstrual irregularities, when it was not. In November, 1918, the company pleaded guilty and was fined \$5.—[*Notice of Judgment No. 6713; issued April 9, 1920.*]

Marshall's Pain Drops and Other Nostrums.—Irving J. Carter, who did business as the M. W. Marshall Medicine Co., Redgranite, Wis., shipped in August, 1917, a number of nostrums which were misbranded. The Bureau of Chemistry analyzed these and reported on them as follows:

"Marshall's Unequaled Pain Drops."—This was found to consist essentially of red pepper, opium, ammonia, alcohol and water with rosemary flavoring. The nostrum was falsely and fraudulently represented as a cure for rheumatism, neuralgia, cholera morbus, all bowel complaints, sore throat, spinal disease, diphtheria in its most malignant form, liver and kidney complaints and various other conditions. It also was said to "contain no poisonous . . . matter" when it actually contained 2 grains of opium to the ounce.

"Marshall's Lung Syrup."—This "syrup" was found to consist essentially of morphin sulphate, ammonium chlorid, vegetable extractives, glycerin, syrup and flavoring material. It was falsely and fraudulently represented as a cure for consumption, asthma, whooping cough, pleurisy, croup, etc.

"Dr. J. C. Brown's Unequaled Liquid Drops."—The "drops" were found to consist essentially of red pepper, ginger, oil of sassafras, camphor, ammonia, trace of morphin, alcohol and water. They were falsely and fraudulently represented as a cure for sick and nervous headache, rheumatism, all bowel complaints, spinal diseases, diphtheria, etc., and were also labeled as containing no poisonous matter when in fact they contained 2 grains of opium to the ounce.

"Marshall's Blood and Liver Pills."—These pills were found to consist essentially of aloes and other plant material, chalk, sugar and starch. They were falsely and fraudulently represented as a cure for inflammation of the liver, stoppage of the menses, "irritable vindictive feelings and passions," kidney disease, nervousness, fevers, dyspepsia, etc.

"Egyptian Oil."—This was found to consist essentially of linseed oil with volatile oils, including sassafras and cedar oils and camphor. It was falsely and fraudulently represented as a cure for piles, diphtheria, coughs, colds, earache and erysipelas.

"Arctic Oil Liniment."—This liniment consisted, essentially, of a liquid in two layers. The upper layer contained kerosene, linseed oil, castor oil and camphor; the lower contained alcohol, ammonia, water, plant extract and a trace of

iodin. It was falsely and fraudulently represented as a cure for diphtheria, rheumatism, catarrh, all kinds of lameness, etc.

"Rheumatic Oil."—This also separated into two layers. The upper layer was found to consist essentially of kerosene, linseed oil, castor oil and camphor; the lower to contain alcohol, ammonia, water, plant extract and a trace of iodine. It was falsely and fraudulently represented as a cure for rheumatism, neuralgia, colic, nervous headache, diphtheria, spinal and hip complaints, colic and distemper in horses, etc.

In June, 1919, Irving J. Carter pleaded guilty and was fined \$50.—[*Notice of Judgment No. 6748; issued April 9, 1920.*]

Correspondence

THE USE OF DRUGS IN OIL

To the Editor:—During the last winter I have been carrying on investigations in the use of drugs in oil, subcutaneously, intramuscularly and intravenously. Although the work has by no means reached a definite form to warrant publication as a completed investigation, I am, nevertheless, prompted to communicate the present results in this preliminary way, because it would be well for other hands to repeat whatever results may have been reached thus far.

In brief, it has been found that the local action of drugs, notably epinephrin, and local anesthetics, such as procain, exhibit a strikingly prolonged drug effect when the drug is administered subcutaneously and in an oil vehicle. It has been possible, therefore, to use epinephrin in oil for such clinical conditions as bronchial asthma, certain urticarial eruptions and in certain types of pneumonia, the method being to establish a local subcutaneous depot of epinephrin in oil, and to procure rather continuous epinephrization effects by repeating the subcutaneous inoculation every eight to twelve hours. With the collaboration of Dr. Theodore Blum it was possible to produce local anesthesia without apparent ill or toxic effect, for a duration of from ten to twelve hours, using the local anesthetic (procain) in oil.

Intravenously, it has been possible to give as much as 10 c.c. of olive oil at one time to a dog and to repeat this dose every third or fourth day, until as much as 100 c.c. has been administered. In rabbits the danger of fatal embolization from the intravenous use of oil is very great, while in dogs this is not so. In man, oil was administered intravenously in doses of 0.25 to 1.5 c.c. in a very small group of cases with no apparent signs or symptoms of embolization.

The intravenous effect of giving a drug in oil, in general, is to produce a gradual, uniform, even and prolonged effect, of a less intensity as compared with the administration of the same drug in aqueous solution, in which the effect would be abrupt, irregular, erratic, rather transient, and of striking intensity. Also, it has been demonstrated that increasing amounts of oil, when added to a definite and constant amount of drug, will diminish the intravenous effect of the drug until no intravenous effect is observed when sufficient oil is used. In other words, within limitations, the less oil used for a definite amount of drug, the more marked the intravenous effect. We have worked mainly with epinephrin, crystalline strophanthin, and to a lesser degree, with nitroglycerin and pituitary extract.

The drug with oil is embolized in the pulmonary capillary bed. We infer that the different pharmacologic action noted from the intravenous use of epinephrin in oil, for instance, as compared with the effect of the same drug in aqueous solution, is probably due to the fact that the drug in oil is carried to the pulmonary capillary bed and there enmeshed to form a local depot.

H. R. MILLER, M.D., New York

THE MENACE OF THE HOMICIDAL DEFECTIVE

To the Editor:—The lamentable assassination of our distinguished colleague, Dr. James W. Markoe, once more shows us the nonsense of our present insanity laws. I enclose a circular which the Brooklyn Neurological Society is sending to every hospital staff and every county society in New York, asking their cooperation in a fight for rational laws dealing with not only our mentally ill patients, but in criminal cases as well.

The agitation for a correction of our present defective insanity laws and procedure should be nation wide.

JOHN F. W. MEAGHER, M.D., Brooklyn.

The circular reads:

For years this society has advocated a readjustment of our insanity laws, not only for the welfare of our patients, but for the protection of society. Insanity, as it is usually termed, is a medical and not a legal problem. As the laws now stand, a judge or a jury has the deciding opinion as to whether a man is sane or insane; safe to be at large, or unsafe; and neither by education nor by training is either competent to decide. Most judges, having sound common sense, realize this and prefer to abide by the opinions of psychiatrists. There are a few who do not. Some of the most dangerous types of insanity—particularly paranoid conditions without deterioration—are the most difficult ones to diagnose.

Not infrequently such cases are merely asked in court whether they are insane, and on replying in the negative, are discharged forthwith! And a potential homicidal patient is thrown back on to society! We as physicians are helpless, for in this branch of medicine—psychiatry—a judge or jury are by our present laws clothed with superior diagnostic powers!

The Medical Society of the County of Kings, with a membership of one thousand physicians, indorsed our attitude, and in February so notified the governor. But unless all physicians, individually and collectively, will interest themselves in this subject, and interest both the press and the public, our efforts will not bear fruit. Instead, the present laws and the present procedure will remain as they are to the detriment of our patients, and a danger to society.

Will you not send resolutions to the governor, and to the members of the legislature, asking for an investigation into our insanity laws?

For let it be reiterated again, that insanity is a mental disorder—a medical problem—rather than a legal one. Personally, I know that most members of the bar agree to this. There should be no division of authority.

JOHN F. W. MEAGHER.

President, Brooklyn Neurological Society.

"OXYGEN INFLATION OF THE PERITONEAL CAVITY"

To the Editor:—With reference to the experience described by Dr. Armitage Whitman (THE JOURNAL, April 10, 1920, p. 1021) we would say that it is ill advised for any patient who has had the peritoneal cavity inflated with oxygen to assume the erect posture for at least twenty-four to thirty-six hours after the roentgen examination. For any one to submit to inflation and then maintain an erect posture, attempting to carry on his business and walking to and from his office to the hospital, would be, to say the least, extremely dangerous. In our attempt to render inflation an office procedure we have of late deflated our patients, in which case they are almost immediately relieved and may assume the erect posture much earlier. Deflation, with a few hours' rest in the recumbent posture, would have given Dr. Whitman the much sought for relief.

WILLIAM H. STEWART, M.D., ARTHUR STEIN, M.D.,
New York.

"TUBING AS A CAUSE OF REACTION TO INTRAVENOUS INJECTION, ESPECIALLY OF ARSPHENAMIN"

To the Editor:—In THE JOURNAL, April 10, 1920, appeared an article under this title from the pen of Stokes and Busman, in which the attention of the profession is called to reactions due to new rubber tubing. Permit me to state that I can fully corroborate their views, not on experimental grounds such as is furnished by the authors, but from a

purely practical experience. A number of years ago, at least four or five, we were struck out of a clear sky by a number of reactions of the nature so vividly pictured by Stokes and Busman, most of them accompanied by herpetic eruptions. This happened in my service at Mount Sinai Hospital, and caused the closest scrutiny into technical errors, toxicity of drug, and the so-called "Wasserfehler," in which I was assisted by Dr. S. Bookman, physiologic chemist of the pathologic department of the hospital. All other causes having been excluded, I came to the conclusion that the reactions were due to new rubber tubing, a suspicion which was fortified by a subsequent analogous experience.

Since that time it has been the standard rule at Mount Sinai Hospital not to use new rubber tubing for intravenous injections until after it has been boiled in soda solution on three successive days for one hour each day.

We believe that by this procedure we have eliminated the so-called tubing reactions.

HERMANN GOLDENBERG, M.D., New York.

THE MEANING OF NONA AS APPLIED TO LETHARGY

To the Editor:—In Flexner's recent article on lethargic encephalitis (THE JOURNAL, March 27, 1920, p. 865) there is a reference to the obscurity of the term "nona," applied to this disease in southern Europe, and a philological surmise that it is really a mispronunciation of "coma." This seems to me a bit far fetched. I think there is a clearer etymological explanation. About thirty years ago, in 1890 when the African sleeping sickness was first called to the attention of students of tropical medicine, there was an epidemic of lethargy among the silkworms in southern France and northern Italy. At Strasbourg, where I was studying, this was spoken of as *Schlafsucht* (*Schlafsucht?*) *der Seidenraupen*, or lethargy of silkworm caterpillars. In Italian, this form of the worm is called "nona," in French, "nonne." There was a great deal of discussion as to a possible common cause of this condition, "malattie de la nona," and human sleeping sickness, and some confusion in the application of the term. It seems quite reasonable to surmise that *malattie de la nona*, or "nona" for short, at first correctly applied to the lethargy of the silkworm, was finally made to include human lethargy as well. This explanation is offered to Professor Flexner for what it may be worth.

PERCY FRIDENBERG, M.D., New York.

FACTS LEADING TO PUBLICATION OF "ARMY FROWNS AND SMILES"

To the Editor:—Will you please be equally as fair to me and publish this reply in your next issue, as you were in publishing the article written by Surgeon-General Merritte W. Ireland in a recent issue regarding my book?

It is unnecessary to enter into a lengthy discussion of the issues involved; suffice it to say, everybody will agree that it is most unusual for a sane man near 34 years old to make such bold statements as I do in my book and then not only sign them but also add to his signature a "sworn affidavit that they were true," unless he knew whereof he spoke.

There are two clear, outstanding reasons why I was not allowed to testify in my own behalf, not even reprimanded for "making false statements," given an honorable discharge from the army two months after having been branded as a liar, and then refused a thorough investigation by the leading government officials of the United States: First, because they are the biggest bunch of back-boneless, pussy-footed white-washers that ever held power in any nation, so far as I know, so help me God. Second, because they knew full

well that I could prove the statements made in my book. Therefore my appeals for justice have been ignored or refused.

DOLPHUS E. COMPERE, M.D., Dallas, Texas.

[NOTE.—Possibly we ought to apologize for printing this communication; we publish it that we may be considered "equally as fair."—ED.]

COMPULSORY VACCINATION

To the Editor:—Compulsory vaccination is repugnant to the popular conception of our institutions. A small minority of our people object to it on business, religious or moral grounds, and a rather extensive minority heedlessly neglect it, so that I suppose today a third of our population is unvaccinated. It is doubtful, even if the courts sustained a compulsory vaccination law, whether it could be enforced with any useful degree of efficiency. Under such circumstances, nothing but the compulsion of fear will drive these recalcitrant ones to seek protection against this dread affection; for, so long as the state takes on itself to protect them by isolation and quarantine of the infected ones, so long will this efficient safeguard be neglected. And my suggestion is that they be driven by personal fear to seek this protection voluntarily. To that end I would repeal all law aimed at smallpox, and leave its victims free to mix indiscriminately with society; but I would provide by law for free vaccination to all comers.

WILLIAM B. ELY, M.D., Ainsworth, Neb.

"MEDICINE A HUNDRED YEARS AGO"

To the Editor:—In the abstract of Deelman and Delprat's paper (THE JOURNAL, April 17, 1920, p. 1138), the allusion to operations by Dupuytren and Larrey for kidney stone should read bladder stone. The first attempt even for renal calculus by Durham (London) was not made until 1870, and the first success was by Ingalls (Boston), Nov. 8, 1873.

J. RAWSON PENNINGTON, M.D., Chicago.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

DEFINITION OF ANOCI-ASSOCIATION, METABOLISM, HORMONES AND VITAMINS—EPINEPHRIN TEST OF GOETSCH

To the Editor:—I shall be obliged to you for information on the following:

1. What is anoci-association; its philological derivation; different forms, applications, etc.?
2. A good definition of metabolism; the different kinds — "basal metabolism," etc.; philological roots; scientific applications, etc.
3. What are hormones; philological derivation; classification, names of those known; practical application?
4. What are vitamins; derivation of this word; classification, application, known kinds, etc.?
5. What is the epinephrin test of Goetsch; technic and clinical applications?

A. I., Ciudad del Carmen, Camp. Mexico.

ANSWER.—1. "Anoci-association" is coined from *a* (Latin privative particle) + *noci* (Latin *nocere*, to injure) + association (Latin *associatio*). Noci-association is the unconscious discharge of nervous energy under the stimulus of trauma, especially in surgical shock. The term anoci-association was introduced by Dr. G. W. Crile to characterize his method of so conducting the anesthesia and managing the operation that this injurious nervous discharge is prevented and counteracted. The procedure contemplates isolating the operative field from the brain by blocking the conduction of harmful sensory and traumatic impulses through

the use of a proper local anesthetic. The patient is gently managed before operation, and if no contraindication exists, a preliminary injection of morphin or morphin and scopolamin is made. When the patient is under the influence of the anesthetic (Dr. Crile prefers nitrous oxid anesthesia), the field of operation is blocked by infiltration with procain (novocain), 1:4,000. The operation is conducted with gentleness, so as to avoid any unnecessary trauma. At the close of the operation a local injection of quinin and urea hydrochlorid avoids nerve exhaustion from after-pain and post-operative stimulation.

2. The term "metabolism" is derived from the Greek (*μεταβολή*, change). It is the act or process by which, on the one hand, the stable nonliving food is built up into complex and unstable living material, and by which, on the other hand, the living matter in protoplasm is broken down into less complex and more stable substances within a cell or organism. Metabolism has been divided into constructive metabolism (anabolism) and destructive metabolism (catabolism). The former comprises the processes by which food substances are converted into protoplasm, while catabolism is the means by which protoplasm breaks down into simpler products as waste or excretory products. In a broad sense, metabolism includes all processes involved in the maintenance of animal life. Basal metabolism is a measure of the energy metabolism of a normal fasting person at rest. It is determined by ascertaining the heat production or gaseous interchange, and is expressed in calories per kilogram of body weight.

3. The term "hormone" was introduced by Prof. E. H. Starling to characterize a group of chemical substances which, formed in one organ, are carried by the blood stream to an associated organ and there excite a specific functional activity. The word is coined from the Greek (*ὁρμῶν*, arouse or excite). The active principles of internal secretions are hormones. Those which have been described are secretin (gastric hormone), hormones of the liver, pancreas, kidney, testis, ovary and corpus luteum, epinephrin and the active substances of the thyroid apparatus, the thymus gland and the pituitary body. The rational treatment of diseases of the ductless glands by organotherapy is based on recognition of the physiologic activities of the hormones.

4. Vitamins (from *vita*, life, and *amin*) are a class of substances of unknown chemical composition, believed to be necessary to normal nutrition and growth, and absence of which from the diet, it is stated, produces certain deficiency diseases, such as beriberi, scurvy and rickets.

5. The test referred to is that called "skin reaction of Goetsch." Eight minims of a 1:1,000 solution of epinephrin are diluted with an equal quantity of sterile water and injected hypodermically into the arm. Immediately there is formed an area of blanching around the point of injection, and about the margin of this usually a red areola gradually shading off into the surrounding tissue. In about half an hour the center of the white area becomes bluish gray to lavender, and at the end of about one and a half to two hours the red areola takes on the bluish or lavender color, while that in the center disappears. This lavender areola remains for about four hours from the time of injection and is the most characteristic part of the test. Accompanying the local reaction may be increase in pulse rate, with palpitation of the heart and an exaggeration of the tremor and nervous symptoms in general. The test is designed to elicit evidence of hyperthyroidism.

MARINESCO AND OGILVIE METHODS OF INTRASPINAL THERAPY

To the Editor:—Please describe the Marinesco and the Ogilvie technics for intraspinal therapy with neo-arsphenamin and arsphenamin. Please omit name in published answer.

W. S. R., Charleston, W. Va.

ANSWER.—The method of Marinesco, which Minea assisted in elaborating, was first published in the *Zeitschrift für physikalische und diätetische Therapie* (17:194, 1913) and soon after in the *Bulletin de l'Académie de médecine* (71:259, 1914). It consisted in the addition of from 6 to 12 mg. of neo-arsphenamin to 2 c.c. of the blood serum of the patient, after this had been inactivated. The mixture was placed on the water bath at 37 C. for forty-five minutes, and was then injected into the subarachnoid space. An injection was made every seven or eight days for as long as seemed indicated.

Ogilvie's method was first described in *THE JOURNAL*, Nov. 28, 1914, p. 1936. The technic employed is as follows:

About 50 c.c. of blood are drawn into a centrifuge bottle by means of a McRae vacuum needle. The bottle is immediately placed in a large centrifuge and the fibrin and cellular elements are thrown down. It requires a speed of about 3,000 revolutions for fifteen minutes to produce a perfectly clear serum. It is rarely necessary to centrifuge more than once if the blood is freshly drawn, but the process should be repeated if the serum is not absolutely free from cells and fibrin. To 15 c.c. of serum is then added the amount of arsphenamin to be given. This is done by mixing the arsphenamin as for an intravenous treatment, using freshly distilled and boiled water, and bringing the total quantity up so that each 40 c.c. of the solution will contain 1.0 dg. (0.1 gm.) of the drug. Each cubic centimeter of this solution will then contain 2.5 mg. of arsphenamin. With a 1 c.c. pipet, graduated into tenths, the desired amount can be readily measured from 0.25 mg. upward. In adding the sodium hydroxid it is of the greatest importance to use only the exact amount required to alkalize the solution very faintly. When this has once been determined by testing with litmus paper, the sodium hydroxid should always be added quickly, and not drop by drop. It is also very important that the temperature of the arsphenamin and serum be the same when the two are mixed. The serum is then gently agitated to mix the two thoroughly, and is placed in a thermostat at 37 C. for forty-five minutes. From this it is placed in a thermostat at 56 C. for thirty minutes. It is now ready to be given intraspinally, and it should be used as soon after preparation as possible. Under no circumstances should a serum be used that is more than three hours old.

BENEDICT'S BASAL METABOLISM DETERMINATION

To the Editor:—What is the Benedict method of basal metabolism determination as referred to by Dr. G. W. McCaskey in the opening sentence of his article in *THE JOURNAL*, April 3, 1920, p. 927?

FRED B. MORGAN, M.D., Clinton, Iowa.

ANSWER.—This method is based on the determination of the respiratory exchange by means of a calorimeter, this exchange being accepted as an index of alterations both in the character and in the amount of the basal metabolism, showing oxygen intake and carbon dioxide output. The method, which is complicated and can be performed only in a properly appointed laboratory, is described fully by Benedict in a number of articles. The more important of these are:

URTICARIA FOLLOWING USE OF PROCAIN

To the Editor:—Has the use of procain ever produced severe urticaria, even running to very pronounced angioneurotic edema?

H. C. AREY, M.D., Excelsior, Minn.

ANSWER.—Many cases are recorded in which drugs have caused urticaria, but procain is not on the list. Drug urticaria is presumably an anaphylactic reaction. It has followed administration of all sorts of drugs, when taken by mouth or when injected subcutaneously or intradermally. Angioneurotic edema, which is really a giant urticaria, has also been caused by drugs.

A SMALL COMMUNITY HOSPITAL

EDWARD F. STEVENS, A.I.A.

BOSTON

Small communities at a distance from the larger cities are often greatly handicapped by the lack of adequate facilities

Fig. 1.—Front view of building (from architect's drawing): Exterior walls are of red brick with roof of red tile; exterior woodwork is painted white; the colonial style is especially adapted to this building, because of its prominent site and spacious grounds.

for the care of the sick and by lack of provision for operation and emergency treatment. Philanthropic citizens, with big hearts, but often with limited means, try to fill this need by securing rooms in an office building or a dwelling house, and the temporary hospital is established and much excellent service rendered. The office building or residence, however, not having been designed for the purpose, and having been built without regard to hygiene or convenience, fails to function properly. There is much lost motion and lack of complete service, and oftentimes a more retarded recovery than with a building planned for the purpose. The community in which the little hospital here illustrated is to be built has been served by the "office building" type of hospital, and while good results have been accomplished, the new hospital will undoubtedly relieve much suffering.

This hospital is located on a commanding site, away from the noises of business and traffic, with sunny exposure. The exterior of the building is in the southern colonial style of architecture, with the body of red brick. The finish of the portico, cornice and airing balconies is of wood, painted white. The roof is of red tile. The interior finish will be simple in character, with due regard to hygienic construction and ease of maintenance. The floors will be covered with

on the first floor, is quite complete, and is sufficiently removed from the entrance to avoid annoyance from that source. From the same section, the roentgen-ray department is approached. The staff room serves as a surgeons' dressing-room. The office is sufficiently near for proper administration. The remainder of the first floor is devoted to the kitchen, dining-rooms, heater and storage rooms. The rear entrance serves as an ambulance approach. While there is

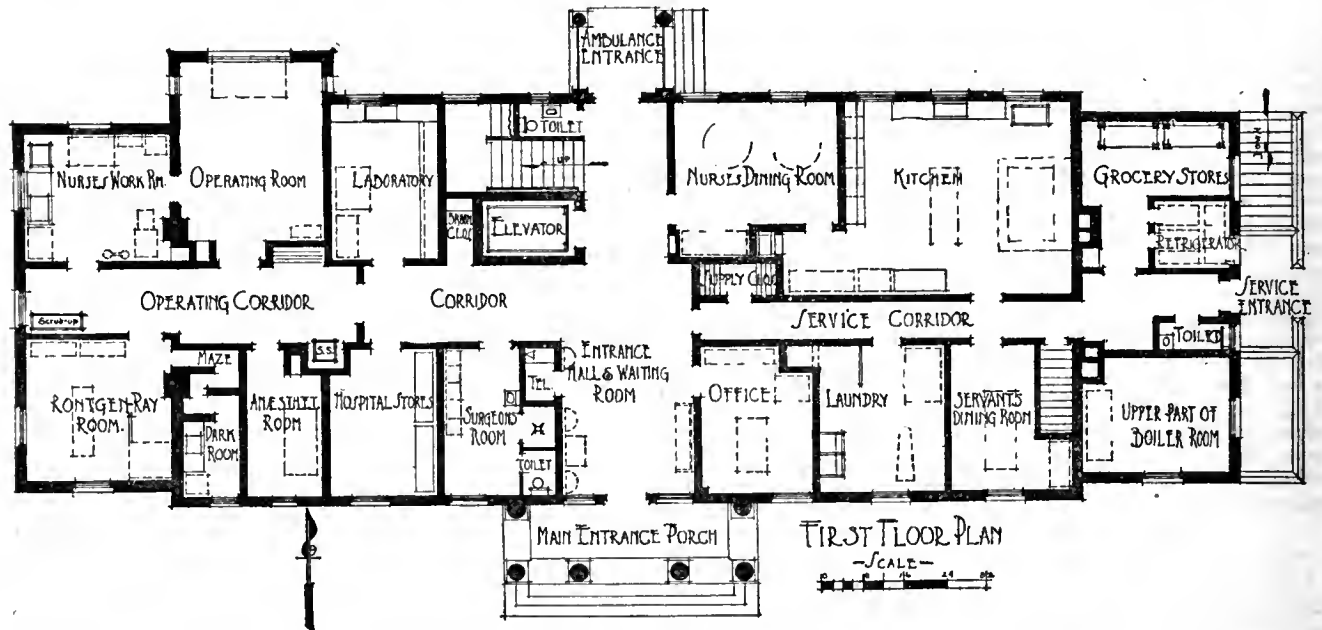

Fig. 2.—First floor plan: All of the administrative functions are provided for on the first floor; note the compactness and convenience of the arrangement; the placing of parts with relation to each other is worthy of study.

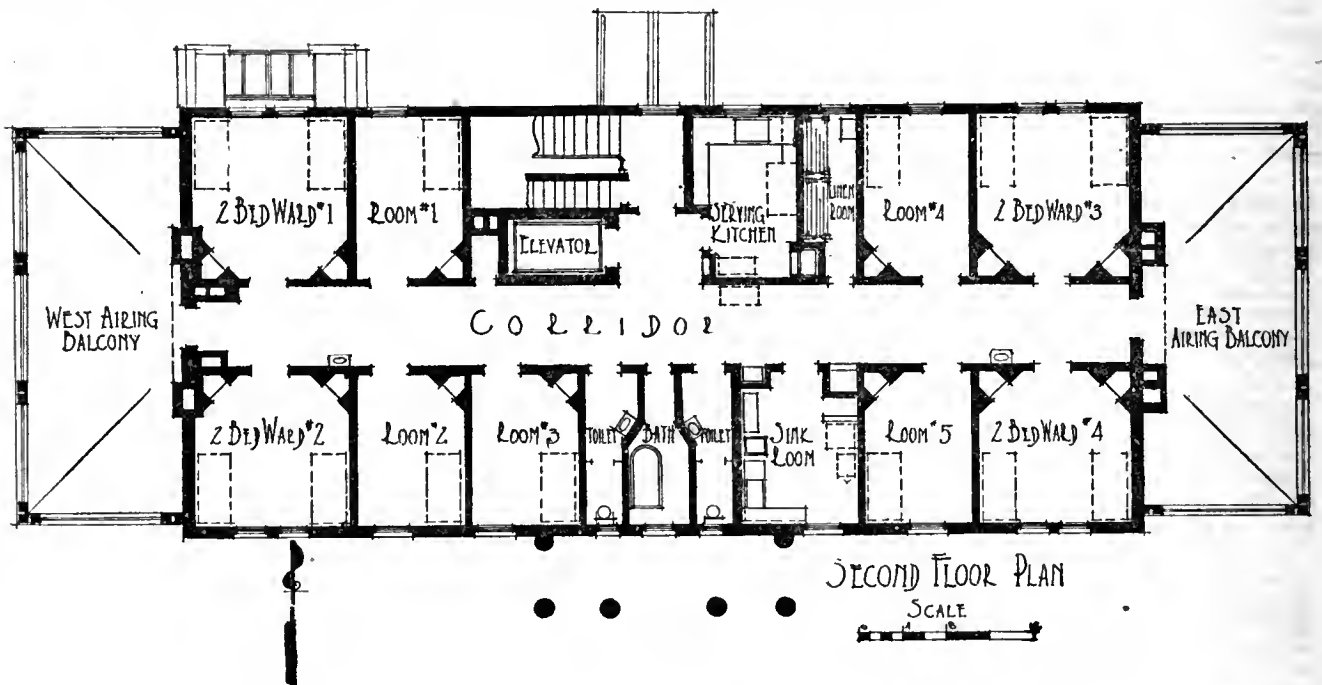

Fig. 3.—Second floor plan: Attention is called to central location of stairway, elevator, serving kitchen, toilets and bath, there are five private rooms and four two-bed wards; at each end is a large airing balcony.

linoleum, and the doors will be of the no-panel hospital type. The walls of the surgical department will be enameled, and the floors will be of tile or terrazzo. The colors employed on the walls will probably be delicate grays or tan. The hardware is to be special hospital type.

The placing of all of the administrative and surgical treatment departments on the first floor allows the exclusive use of the second floor for patients. The operating department,

space provided for an elevator, the stairs are made broad and are easily ascended.

On the second floor are the rooms for patients, divided into several three-bed wards and private rooms. The serving kitchen, sink room, toilets, bath and linen room provide the necessary accommodation for the proper service for the patients. At each end of the building, large airing balconies enable all patients to be brought into the open air.

Social Medicine and Medical Economics

SOCIAL PEDIATRICS*

HENRY L. K. SHAW, M.D.

Clinical Professor, Diseases of Children, Albany Medical College
ALBANY, N. Y.

In no branch of modern medicine has there been so much progress as in that of the prevention of disease. Emphasis is now being largely directed to health rather than to disease. The triumph of the medical corps in the World War both in this country and abroad over that invisible and insidious enemy—disease—was due largely to preventive measures. Every returned soldier and sailor has received practical instruction in public health, and a new vision of the domain of medicine came to all medical officers who entered the service.

Sir George Newman expresses the present trend of thought when he says that the "first duty of medicine today is not to cure disease but to prevent it." All our human knowledge and experience should be applied to the prevention of disease. Herein lies our greatest service to mankind. To cure is splendid and praiseworthy, but to prevent disease is Godlike and magnificent. Dr. Lyon writes that "some physicians fail because they take a narrow and individualistic view of their work. They get the patient so close to their eyes that they cannot see the public. They see their trade, but fail to recognize their profession." In the struggle for existence and the necessity for making a livelihood, the attitude of the medical profession toward social problems is likely to be narrow, selfish and individualistic. We need a broader vision, and we should appreciate that the claims of the health of the public are greater than those of any individual. Gittings, in an address on "Physicians and Social Service," said that as a class "we have been slow to recognize the importance of many of the lessons taught by sociology, and have allowed our study of disease, the figure in our limelight, to blind us to much of the background out of which disease emerges. The art of medicine of yesterday was too conservative in its conception of its true functions. So far as it has gone, the prevention of disease has proved to be one of the greatest achievements of the science of medicine of today."

Not one of us will dispute this statement; but what is being done to spread the gospel of public health among the physicians of this country? They must be educated, or rather reeducated, in modern medical social problems. A physician engrossed in private practice with its many demands and responsibilities will not have much leisure in which to take up any new line of study. The most satisfactory method lies in the medical school. The mind of the medical student is receptive and plastic, while it is hard to teach new tricks to old dogs. Dr. Ira S. Wile, in an address at the meeting of this section at Rochester in 1912, said that "medical schools exist for the purpose of supplying the community with men who are trained in caring for the public health. If the schools fail to teach their students the methods of preservation of life, they fall short of their ideal purpose. The position of the physician is altering, in that the community no longer regards him merely as an individual, capable of curing individual diseases, but as a specially gifted man, capable of guiding the public in and to health." The physician should be looked on as the leader in public health activities; but this work in a community

can never be elevated to a higher degree than the medical profession raises it. A stream is no purer than its source, and we must elevate and educate the source.

OPPORTUNITIES OPEN TO MEDICAL MEN IN SOCIAL WELFARE WORK

My object in this paper is to present a plea for systematic training in social pediatrics in our medical colleges. The prospective medical student should be directed in his pre-medical course to study sociology and economics and obtain a comprehensive grasp of the organization of modern society. This subject should appeal very strongly to those of us who specialize in diseases of children. By virtue of our training and experience we should take an active part in all social welfare agencies. The child forms the basis of most of our public health work. The foundation for many of the diseases and most of the defects of later life is laid in early childhood. The study of the child in health, the preservation of health and the prevention of disease are as essential in the practice of our profession as that of the study of the diagnosis, pathology and treatment of disease. We have not realized the great opportunities for service and the fulfillment of our highest professional ideals in directing and assisting social welfare and educational work. By our indifference we have allowed the nonmedical social worker to grasp a great opportunity and gather all the honor and glory. The physician, and not the social worker, is the logical arbiter of all problems relating to health. He is the one who should advise and direct and perhaps supervise the activities of health and sociomedical activities. He can uphold the honor and dignity of his profession on a loftier level than by simply being a purveyor of pills. Social medicine opens up great opportunities and new territories for service to members of the medical profession.

Dr. Richard Bolt, general director of the American Child Hygiene Association, proposes as an ideal scheme for the education of medical students in the essentials of infant and child welfare work:

1. A clear understanding of the structure of modern society, with special emphasis on the changes which are taking place in medicine from an individualistic to a community service.
2. Familiarity with the general methods of all social agencies working for the welfare of the child.
3. A knowledge of the causes of infant mortality, and the most approved methods of prevention.
4. A good working knowledge of obstetrics, especially in its relation to the nursing and social needs of the community.
5. Experience in maternity (prenatal) service.
6. A course of pediatrics, laying stress on the fundamentals in infant hygiene and infant feeding.
7. Thorough instruction in modern pediatric methods, with actual experience in a babies' dispensary and in an infant welfare center for prophylactic work.

I wish to submit a syllabus of a course of instruction in social pediatrics which is being carried out at the Albany Medical College. It is not perfect or complete by any means, but it will serve to illustrate the possibilities of such a course and point out some of the functions of social pediatrics.

INSTRUCTION IN SOCIAL PEDIATRICS AT ALBANY MEDICAL COLLEGE

The Child in Health:

Anatomy and physiology of infancy and childhood.
Difference from adults.
Growth and development.
Periodic physical examination.

Vital Statistics and Demography:

Birth registration. Stillbirths. Illegitimacy.
Methods of improving.
Mortality statistics:

Rates at different ages and seasons.
Effect of season and climate.

Mortality During Childhood:

Definition and significance.
Distribution in the United States and other countries.

*Read before the Section on Pediatrics at the One Hundred and Sixty-Fourth annual meeting of the Medical Society of the State of New York, New York, March 23, 1920.

General causes: Prenatal; natal; postnatal; preventable; nonpreventable.
 Causes by age periods.
 Effect of poverty and ignorance.
 Influence of domestic and social conditions:
 Age and nationality of mother.
 Effects of alcohol and venereal disease.
 Food; nursing; milk; proprietary foods; diet.
 Preventive methods:
 The mother (maternal work; number of children; age of mother).
 The child.
 The surroundings.
 Social conditions: housing, sanitation, etc.

Prenatal and Maternity Care:

Childbirth statistics.
 Causes of death: Baby: fetal and congenital; mother.
 Instruction of expectant mothers.
 Systematic examinations.
 The mother in industry.
 Regulation of midwives.
 Prenatal clinics and maternity centers.
 Care of mother during pregnancy.
 Care of mother: at confinement; hospital.
 Prevention of blindness.
 The prenatal nurse.

Infant Hygiene:

Foundling asylums; baby farms; boarding out and adoption; infant hospitals.
 Instruction of mothers: breast-feeding, etc.; proprietary foods.
 Importance of pure, clean and safe milk.
 Infant welfare stations: municipal; private.
 Day nurseries: objects: regulation and inspection; the child welfare nurse.

Child Hygiene:

Preschool period: diet and nutrition; physical examination; correction of defects; posture, teeth, adenoids, tonsils, rickets; nursing schools.
 School age:
 Medical school inspection; physician-nurses.
 Periodic examinations: weight, height, etc.
 Early treatment of defects: vision, hearing, nose and throat, skin, etc.
 Dental clinics; mouth hygiene.
 Treatment of dental defects.
 Prevention of infectious diseases.
 Diet and nutrition; school lunches.
 Mental examination; special classes.
 Physical training; open air classes.
 Supervised play; recreation and playgrounds.
 Health education of teachers and pupils.
 Little mothers' leagues; Junior Red Cross; Crusaders.
 School sanitation, ventilation, fumigation, lighting, cleaning.
 Adjustable seats and desks.
 The school nurse.

Care and Education of Abnormal Children:

Backward and mentally deficient children.
 Institutional care; commitment.
 The crippled child.
 The blind child.
 The deaf and dumb child.
 The delinquent child; juvenile courts.

The Child in Industry:

State and national legislation.
 Approved standards of child labor.
 Employment certificates.
 Educational and physical requirements.
 Supervision and periodic examinations.
 Widows' and mothers' pensions.

Tuberculosis in Children:

Physical examinations.
 Protection of exposed children.
 Home supervision.
 Preventorium; sanatoriums; day camps, etc.
 Follow-up work.

Child Welfare Propaganda:

Extension and educational work.
 Exhibits, posters, moving pictures, newspaper publicity, pamphlets, etc.
 Lectures and demonstrations.
 Administration of Child Welfare centers.
 National Child Welfare Organizations:
 American Child Hygiene Association.
 Child Health Organization.
 Child Labor Committee.
 American Public Health Association.
 Parent-Teachers Association.
 State and local child welfare organizations.

Health Agencies:

Federal:
 Children's Bureau.
 U. S. Public Health Service.
 Department of Education.

State:

State department of health.
 Division of child hygiene.
 Vital statistics.
 Public health nursing.
 State board of charities.
 State department of education.

Municipal:

Health department.
 Board of education.
 Child welfare stations.

Private:

Day nurseries.
 Maternity centers.
 Playground associations, etc.

POSSIBILITIES OF COOPERATION

Clinical facilities for demonstration and practical instruction can be provided in any city large enough to maintain a medical college. The city bureau of health could make available its various departments, including child welfare stations, tuberculosis clinics, milk and dairy inspection, vital statistics, etc. The bureau of education could provide opportunities for the study of the health and hygiene of the school-child, dental clinics, nutrition classes, and the follow-up work of school nurses. Private agencies that support day nurseries, playground associations, orphan asylums, infants' homes and other places of child welfare work would cooperate in this work of instruction. In fact, the interest of all agencies engaged in health, welfare and relief work could be secured and a full cooperation arranged.

CONCLUSION

We are now entering on a world wide era of reconstruction in which the subject of health will receive more attention than it has in the past. The medical profession must advance with the spirit of the times and be prepared to take an active and leading part.

Let us, therefore, by our own interest and influence hasten the day when social pediatrics shall take a prominent place in the curriculum of our medical schools. The physicians of the next generation will then be equipped for greater service for mankind.

361 State Street.

COMPULSORY HEALTH INSURANCE

At a social insurance session of the National Civic Federation, presided over by Samuel Gompers, Mr. James W. Sullivan of the American Federation of Labor made the following points:

The state may justly carry out measures intended to protect all its citizens alike against the various menaces to health and to control treatment of the sick. In the matter of meeting wage losses, the state may be expected to supervise associations for the purpose, and supply the machinery for such supervision. How much further should it go? The trade unionist stops to reflect when in theory he is brought to the line which sets the wage-workers aside as wards of the state, as subjects of special regulation, and as material for a social machinery run by state officials.

Sickness insurance! What is to be insured? What is sickness? Who is sick? Who is to decide when one is sick? Who is to say when one's sickness is his own fault? Who is to determine justly many questions in the matter of sickness? To what degree is sickness a mere matter of the mind? People of robust mentality ignore the aches and pains which frighten timid people. One's habitual attitude toward sickness counts for much. Some have the doctoring habit, some the "patent medicine" habit, some the habit of ignoring what sends other people to bed. Under any form of sickness insurance, voluntary or compulsory, a certain proportion of the members of any group would quickly develop the habit, to be indulged in to the maximum degree, of being "on the funds."

A fair statement of the present attitude of organized labor is that, in the case of sickness insurance, as with respect to many other propositions, it refuses to take a plunge in support of a project which is part of the program of socialism. Nor is it prepared to support without careful scrutiny measures drawn up by associations not in its membership; it will not approve of any law which will tend to break down its own systems of mutual assistance; it regards the degree to

which the interposition of the state shall extend as a matter to be settled in favor of the principle of liberty of the individual; it resents an indiscriminate classification of wage-earners as objects of public relief; it looks to wider measures than sickness insurance in the social campaign for the reduction of the death rate, the prevention of sickness, the improvement of public methods of caring for the sick and, finally, for the general sharing of the burdens of sickness.

Book Notices

LA RACHIANESTHÉSIE GÉNÉRALE. Par Professeur Thomas Jonnesco. Paper. Price, 4 francs net. Pp. 126. Paris: Masson et Cie, 1919.

This is an exposition of Jonnesco's method of what he calls general spinal anesthesia. The author wishes to make clear that the essential thing is the method he uses and not the particular substance stovain, which is only an adjuvant that may be replaced by any other local anesthetic in which the surgeon may have confidence. The author uses stovain and strychnin sulphate. He lays great stress on having the substances properly prepared. For his own use he has them prepared in separate ampules: a definite amount of strychnin dissolved in 1 c.c. of distilled water in one ampule, and a definite amount of stovain crystals in another ampule. Both, of course, are sterilized. He emphasizes the importance of having the stovain sterilized by heating it to 100 C. on three different occasions. When ready to be used, the strychnin solution, always 1 c.c. in amount, regardless of the quantity of strychnin contained, is mixed with the stovain in the ampule, and solution is favored by gently heating the ampule. When thoroughly dissolved, it is drawn up in the syringe and slowly injected. Four points of election are given for injecting the solution: the inferior lumbar, the dorsolumbar, the superior dorsal and the midcervical, depending on the extent of the anesthesia desired. It is stated that there are no contraindications to the use of the method; but the dose of stovain, as well as that of strychnin, must be adjusted very carefully to the age and general condition of the patient. During five years the author and his associates performed 11,329 operations by this method. Of this number, 1,035 were high or midcervical, and 10,289 low injections. In this number were included operations on all parts of the body, from head to foot. It is asserted that there were only two deaths that could be attributed to the anesthetic, and these, which occurred in the hands of two of his associates, were due, according to the author, to faulty technic from lack of experience, in that too large a dose of stovain was used for cervical injections. Notwithstanding the excellent results that the author reports and the enthusiasm with which he defends them, the method has found few followers outside of his own associates. He himself says: "It is always necessary to bear in mind that spinal anesthesia is not an empirical method and that it is not to be considered a simple maneuver to be executed according to definite fixed rules in advance. The method requires to be applied by a man of science, conscious of his duty, and knowing that he has in his hands an excellent, exact and powerful agent, but only on condition that he take pains to understand it and to employ it intelligently."

RAMBLING RECOLLECTIONS: AN AUTOBIOGRAPHY. By A. D. Rockwell, M.D. Cloth. Price, \$4 net. Pp. 350, with 7 illustrations. New York: Paul B. Hoeber, 1920.

Dr. Rockwell, now in his eightieth year, has been so long out of the active whirl of medical life that one is reminded by this book that he is not only still alive but active so far as writing is concerned. To those who were engaged in practice twenty-five or thirty years ago, the name A. D. Rockwell immediately calls to mind one of the most pretentious and practical books on medical electricity published in this country—Beard and Rockwell's *Medical and Surgical Uses of Electricity*—a book the popularity of which is attested by the fact that it passed through some ten or twelve revisions and editions. It and the miscellaneous contribu-

tions on the subject by these two men had much to do with the wide use of electricity during the last two decades of the nineteenth century. The medical battery—at least the faradic box—was then to be found in the offices of half the physicians of the country. Its uses as a therapeutic agent were almost unlimited, and it was recommended for a variety of conditions, from constipation to ectopic gestation.

The title of this autobiography is descriptive of the book. It is made up of recollections more or less rambling in character. But this is not a fault for the author presents it not as a real biography but rather as comments on men and things, with the story of his own life incidentally woven in. A book of such character—written by a man of wide experience, including that of both private and army surgeon in the Civil War, and extending over three fourths of a century—could not be other than interesting and instructive.

PRÄKTISCHE BAKTERIOLOGIE FÜR AERZTE UND STUDIERENDE. Von Dr. L. Paneth, Assistent am kgl. Institut "Robert Koch" in Berlin. Paper. Price, 8 marks. Pp. 158, with illustrations. Berlin: Urban & Schwarzenberg, 1919.

This is a brief manual describing laboratory technic for diagnosis of infectious diseases. In general it will be of little use for American physicians and laboratory workers, as many of the methods differ materially from those used in our laboratories. Where the methods are the same, descriptions are available in American publications.

Medicolegal

Treatment of Osteomyelitis—General and Special Employment

(*Nelson v. Farrish et al. (Minn.), 173 N. W. R. 715*)

The Supreme Court of Minnesota, which affirms a judgment in favor of the defendants who were sued for alleged malpractice in the treatment of a child afflicted with osteomyelitis in the radius, says that defendant Farrish was called, November 12, to treat the case. The disease grew worse, and, on the 18th, defendant Portmann was called. He attended with Dr. Farrish, examined the arm, and gave directions as to treatment. He did not take full charge of the case, was apparently not expected to return unless called, and, when he left, gave directions that if they "needed him any more to call him." On the 22d he was called again, and came. Dr. Farrish also was present. Dr. Portmann gave some directions as to treatment, but did not come, and apparently was not expected to come again without being called. Dr. Farrish continued to treat the arm. It continued to grow worse, and, December 2, Dr. Portmann was again sent for. He was not at home and, instead, his son came and the next day took the child to a hospital, where he and defendant Portmann performed an operation on the following day. Dr. Farrish's employment then ceased. In January the parents took the child to a hospital in St. Paul, where a surgeon performed an operation in the presence of defendant Portmann, and found it necessary to remove the radius, which was done.

It was conceded by all that the proper treatment for osteomyelitis was by operation, consisting in opening the shaft of the bone and affording drainage of the pus and removal of diseased tissue. The plaintiff charged that the defendants did not advise or suggest that treatment, and did not correctly diagnose the case until the disease had progressed so far that the bone was beyond treatment and the use of the arm virtually lost, whereas it might have been saved. The defendants, on the other hand, insisted that they did promptly diagnose the disease and advised the parents of its true nature, and seasonably advised operative relief, and that the parents objected to any operation, until it was too late to save the arm. The trial judge instructed the jury that if the defendants within a reasonable time made a correct diagnosis and clearly advised the parents of the nature

of the ailment, of the importance of an immediate surgical operation, and of the result likely to follow a refusal, and the parents refused to permit such operation, the verdict of the jury should be for the defendants; but that if the defendants failed to diagnose and treat the child with reasonable and ordinary skill, and such failure resulted in the injury complained of, then the defendants were liable for damages. The supreme court finds no error in this instruction, and holds that the evidence was such as to sustain a verdict for the defendants.

The plaintiff contended that defendant Portmann was employed generally to diagnose, treat and cure, and complained that the jury was instructed that he was called in consultation with Dr. Farrish; but, under the evidence, the supreme court thinks that the ruling was right. However, so far as concerned his liability for what occurred on the occasion of his visits, it was not very material in which capacity he was called. He was called as a physician and surgeon to diagnose the disease and prescribe or direct treatment for its cure, regardless of what Dr. Farrish had done. While he was there he owed the duty to employ reasonable professional skill. The court did not rule or instruct otherwise. There was no claim on his behalf that he had not ample opportunity to diagnose correctly the disease. He claimed that he did so, and advised the family of his diagnosis. In this connection it is pertinent to observe that there was no question but that Dr. Farrish's employment was general. Since the jury found in his favor, it is difficult to see how it could have found otherwise as to Dr. Portmann, whether his employment was general or as a consultant. In no possible view of the case could it be said that the obligation or liability of Dr. Portmann was greater than that of Dr. Farrish. The difference between general and special employment relates mainly to the obligation of the physician to continue his attention. If called generally he must give such continued attention and attendance as the condition of the patient requires. But if called specially and only for the occasion, he owes no duty to repeat his visits or continue his treatment. The court thinks it was the effect of the testimony of the plaintiff's witnesses that defendant Portmann was not expected to return, except when called, and that he owed no duty to do so, and could be held liable for only such damages as resulted from his connection with the case on the occasion of his visits.

Breach of Contract to Furnish Medical Services— Chronic Diseases—Prolapsus

(*Coffey v. Northwestern Hospital Association (Ore.)*, 183 Pac. R. 762)

The Supreme Court of Oregon, in affirming a judgment in favor of the plaintiff for \$1,500 damages, says that this was an action for breach of a contract to furnish the plaintiff medical and surgical services in case of illness. The contract stated that it did not cover chronic diseases. In reply to a letter which described fully the plaintiff's condition, the defendant said, in effect: "Your disease is chronic, and not subject to treatment under our contract; but come down, and if we find it is not chronic we will treat you." The reply was substantially a refusal to treat her under the contract for the disease from which she was suffering, on the ground that it was chronic, and therefore not within the contract. No person in the plaintiff's condition would have gone after having been informed that, if she had the sickness which she claimed to have, she would not be treated. If the trouble was, in fact, a chronic one, the defendant was justified; otherwise, its refusal was a breach of the contract which rendered it liable in damages.

The evidence introduced as to the disease from which the plaintiff was suffering indicated that in 1910 she suffered from prolapsus uteri, and that as a result of an operation she was completely cured of that trouble, and was in sound health when she became a party to the contract with the defendant; that this condition continued for about two and a half years; that later, when the plaintiff did hard work or lifting, she had temporary prolapsus, but that her condition always became normal on ceasing such work. The effect of the plaintiff's testimony was that she had frequent attacks or recurrences of the trouble at intervals, produced by over-

work or lifting, but that the trouble was not continuous. The evidence on behalf of the plaintiff indicated that she was much more susceptible to attacks of this character than the ordinary woman, but this fact alone did not render the disease chronic.

It is a fact well known, even to laymen, that there are persons whose bones are so brittle from disease or malnutrition that they are broken by blows or falls which would do no particular injury to a person whose bones are normal; but it does not follow that such persons have chronic broken arms or legs. Some persons are poisoned by the slightest contact with poison ivy, while others are not affected by it; but it does not follow that the susceptible person is afflicted with chronic ivy poisoning.

A chronic disease is one of long duration or characterized by slowly progressive symptoms. It appeared that the plaintiff's first attack was cured in three weeks by an operation; that she remained in good health for more than two years, and that subsequent attacks were cured by avoiding the causes which produced them. Whether the plaintiff's ailment was chronic was a question of fact for the jury, which was instructed, in substance, that the burden of proof was on the plaintiff to show that she was not suffering from a chronic ailment.

Lastly, it was a forced construction of the contract to say that it required the defendant to render services only in the city where it had a hospital, when three things were promised the members of the association: (1) free hospital service where a hospital was provided; (2) free medical treatment, without any specification as to where it was to be rendered, and (3) free surgical treatment under the same conditions.

Epilepsy Not Ground for Annulment of Marriage

(*Behsman v. Behsman (Minn.)*, 174 N. W. R. 611)

The Supreme Court of Minnesota, in affirming a judgment refusing to annul a marriage contract on the ground that one of the parties thereto was an epileptic at the time of the marriage, holds that proof that the defendant was an epileptic at the time of such marriage was not, in the absence of a showing of fraud on the part of the afflicted party in concealing the epileptic condition, sufficient to warrant a decree of annulment. It holds that, the legislature not having prescribed epilepsy as a ground for the annulment of marriage, and the courts of the state never having recognized that disease as a cause for nullifying a marriage contract, the judgment of the trial court denying such relief was justified, notwithstanding a finding of fact that the defendant was an epileptic at the time of the marriage. The findings of the trial court in this case were, in effect, that the parties were married in 1907; that the issue of such marriage was three children; that the defendant was and had been ever since she was 2 years of age an epileptic; that the disease continued to grow on her until Sept. 3, 1915, when she became insane and was committed to a hospital for the insane; that she was becoming more irrational and violent and was not expected to improve in her condition; that the plaintiff and the defendant lived together as husband and wife until shortly before the defendant became insane, and that the plaintiff did not know that the disease with which the defendant was afflicted was epilepsy until about Sept. 3, 1915. As conclusions of law, the court found that the plaintiff was not entitled to have the marriage annulled, but that he was entitled to the custody of the children, and the supreme court is of the opinion that the judgment should stand. Section 7090 of the General Statutes of Minnesota of 1915 provides that no marriage shall be contracted between persons either of whom is epileptic, feeble-minded or insane, and Section 7107 provides that when either party to a marriage is incapable of assenting thereto for want of age or understanding, or when the consent of either has been obtained by force or fraud, and there is no subsequent voluntary cohabitation of the parties, the marriage may be annulled; but the legislature has not prescribed epilepsy as a ground for annulment of marriage, nor have the courts of Minnesota recognized that disease as cause for nullifying the marriage contract.

MISSOURI STATE MEDICAL ASSOCIATION

Sixty-Third Annual Meeting, held at Jefferson City, April 6-8, 1920

Artificial Anus

DR. W. T. COUGHLIN, St. Louis: A preoperative explanation of the operation to the patient is advisable. The amount of relief to be expected varies with the indication for the operation. Not much benefit to the primary condition is to be expected when the operation is undertaken for cancer of the bowel below. The decision for or against the operation should be left to the patient except when the operation is performed for the relief of acute obstruction.

Autoplastic Repair of Ununited Fractures and Bony Defects

DR. ERNEST F. ROBINSON, Kansas City: Bone surgery has passed through many changes and contradictory phases, but we have at last arrived at a satisfactory rational method in the autoplastic repair of bone. Some fundamental facts have been deduced in reference to the autogenous repair of fractures: 1. Fractures in which good functional results may be secured by external means (and this number in recent years has been greatly increased by modern military splints and devices) should not be operated on. 2. In fractures which cannot be properly reduced and immobilized, autoplastic repair is usually the only safe procedure. All metal devices, Lane plates, nails, screws, clamps and all foreign bodies in bone fractures are a failure, and prevent rather than produce union. Autoplastic graft is resistant to infection. It is absorbed or becomes an integral part of the bone itself. Two methods of bone transplantation may be considered: (a) the bone inlay, as perfected by Albee, or (b) the dowel peg or intramedullary splint. In either or both we must have: (1) an aseptic operative wound; (2) a live transplant from the same individual—preferably with periosteum; (3) actual contact between graft and bone, and (4) perfect and complete immobilization. Usually there is complete absorption with bone organization. Occasionally, early absorption takes place because of specific ferments. My own preference is in favor of the medullary transplant over the bone inlay, as there is less likelihood of infection and no foreign substance (such as catgut or tendon sutures to be absorbed) is left in the wound. In the great percentage of cases, union with satisfactory results can be assured. Such operations are as uniformly successful as are any in surgery.

Traumatic Aneurysm

DR. HERBERT S. VALENTINE, Kansas City: In traumatic aneurysms, particular attention is called to the possibility of hemorrhage from one false aneurysm giving rise to one or even more secondary aneurysms. Couteaud's observations regarding the weakness of the pulse proximal to an arterial lesion may be of value, especially when other localizing symptoms are absent. Contrary to the commonly accepted ideas, it has been found by English surgeons that in many cases simultaneous ligation of vein and artery may be safer as regards both life and avoidance of gangrene, than is ligation of the artery alone.

Treatment of Dacryocystitis by Curettage and Rapid Dilatation

DR. JOHN GREEN, JR., St. Louis: Curettage of the sac and duct as a treatment for chronic dacryocystitis was proposed by Thompson in 1918. This method proved fairly successful in my hands, but some failures led me to supplement this procedure by immediate rapid dilatation of the lacrimonasal duct. The dilated duct thus affords adequate primary and secondary drainage. The operation is facilitated by the use of specially designed lacrimal sac burrs and lacrimal duct reamers.

Subconjunctival Injections in the Treatment of Ulcers and Infected Wounds of the Cornea

DR. W. H. SCHUTZ, Kansas City: The lack of any generally accepted method of treating corneal infections led me to try mercuric cyanid. Dr. E. L. Jones of Maryland for some time persisted in drawing attention to this method, and declares that it has proved the most reliable and effective means of treating the conditions described. The power and healing effects of the injections are thought to be due not to the specific drug itself but to some process in which the drug merely acts to increase the circulatory activities to distend and flush the lymph channels. The advantages of this method may be thus summed up: There is no destruction of corneal tissue; the site of the ulcer, the stage it is in, or the size or any other reserve, need not be considered. The healing is sure and rapid, the transparency of the cornea more marked and scar formation less evident. The influence of the treatment on the subjective symptoms is very evident and positive. Immediately after injection, the pain is more or less of a severe type, lasting from ten to thirty minutes, but made bearable by the application of hot compresses. When the postoperative pain has ceased, further suffering from the disease vanishes entirely in the majority of cases; and in the few instances in which it does not, the amelioration is so positive that the patient seldom fails to express words of gratitude.

The Present Status of Nitrous Oxid Anesthesia

DR. MORRIS H. CLARK, Kansas City: The failure of nitrous oxid to keep pace with ether and chloroform as a general anesthetic is due to difficulty in mechanically handling the gas, and failure to recognize that it is a selective anesthetic not applicable to all cases. It is an anesthetic of details. Nitrous oxid should never be given except in connection with oxygen. Modern apparatus should have these necessary requirements: reducing valves for both nitrous oxid and oxygen, and means of controlling the rate of flow, percentage of mixture and pressure in the breathing bag. Ether attachment should be present in case of need. Ether in small amounts may be used to bridge over more painful procedures, or for stimulation during shock. The amount need not be more than from 1 to 4 drams during the course of a long anesthetic. This small amount produces no harmful after-effects.

Cardiolysis for Chronic Mediastinopericarditis

DR. ELSWORTH S. SMITH, St. Louis: The condition may be recognized through the presence of chronic ascites not explainable in other ways, and physical signs of fixation of heart dulness, diastolic shock, retraction of interspaces about the apex and below the angle of the left scapula, and through fluoroscopic examination. Up to June, 1913, Sommers had collected data on only thirty-eight cases performed abroad

and none in this country, and since that date we have found only one in this country, so that the two cases here reported are the fourth and fifth cases recorded in this country. Among these forty-five reported cases there had been only nine failures, in four of which necropsies revealed errors in diagnosis.

The Actual Caution in the Treatment of Superficial Cancers

DR. CHARLES F. SHERWIN, St. Louis: The only cure for cancer is a total destruction of all its pathologic cells. Any such cells not quickly destroyed by treatment gradually become more resistant and are often stimulated into increased rapidity of growth. Good cosmetic results are desirable, it is true, but quick and certain destruction of all tumor cells is absolutely imperative regardless of any cosmetic result, for cancer let alone or left behind will surely kill. In those types of superficial cancers variously known as rodent ulcers, and epidermoid or basal-cell carcinomas, which tend to remain localized, total extirpation of the affected area together with a strip of normal skin and underlying tissues afford the best possible chance of complete cure. This can be accomplished by clean excision with a scalpel; but if it accidentally cuts into cancer, it will scatter and implant it along any further line of the incision. The electric cautery loop at a dull red heat cannot thus transplant cells, but cuts skin readily, does not char, yet destroys cells 2 or 3 mm. beyond the incision line; controls practically all hemorrhage at once; blocks lymphatics; readily permits gross differentiation of normal and pathologic tissue; obtains the entire lesion at once for microscopic diagnosis, and, with properly regulated heat, is capable of exceedingly fine dissection about tendon sheaths, eyelids, etc. Local anesthesia makes the procedure painless; the postoperative pain is negligible unless bone is involved; the area granulates readily; the scar is often either unnoticeable or a slight smooth depression, or in extensive areas contracts into a raised line. The final result is limited only by the judgment of the operator as to the boundaries of the lesion, a factor likewise necessarily present in any form of treatment. We do not advocate cautery excision in squamous cell cancers in which adjacent lymphatics and glands early become involved, as lower lip, breast and similar types. Soldering irons at dull red heat or less are ideal for large lesions, or for temporary cleaning up of foul, ulcerated, incurable cases. Cauterizing bone is often necessary in far advanced cases, but causes considerably more pain, and is very slow to discharge the sequestrum and heal. Caustics act largely on the surface, are never subject to such accurate control as to depth and boundaries, cause great pain, more often stimulate the tumor to rapid growth, and usually cause an unsightly scar. Radium is often as painful as the cautery wound, never removes the cancer bearing area, requires weeks or months to effect the complete retrogression, occasionally stimulates more rapid growth, and often after apparent cure, nodules recur in the scar. However, it usually conserves adjacent tissues, and its cosmetic results are often equal to or occasionally better than the cautery scars.

Operative Treatment of Carcinoma of the Tongue

DR. V. P. BLAIR, St. Louis: The majority of carcinomas of the tongue are probably mildly malignant, the unsatisfactory results and the high mortality rate being due to late and inefficient operation. Some cases are highly malignant from the onset. Surgical intervention should be undertaken early, with complete elimination of all conditions which suggest the possibility of cancer. These operations may be only a wide local excision, but can be made as radical as can an operation on the breast. The preoperative and postoperative treatment of these patients is of the utmost importance. Careful attention to the details of these will permit of more extensive operations. Roentgen-ray and radium treatments of sufficient activity are helpful adjuvants to surgery.

Summer Diarrhea of Infants: A Study of the Pus Cells in the Stools

DR. JOHN ZAHORSKY, St. Louis: It has been found that the majority of cases of summer diarrhea show a great

increase in the cellular content of the stool. Our study indicates that most of the diarrheal diseases of summer are infectious processes. Adults are a common source of the virus that produces diarrhea. The method of conveyance is by contact, insects and, more frequently, by milk and ice cream.

Feeding of Athreptic Infants

DR. MAURICE J. LONSWAY, St. Louis: In athrepsia or marasmus it is necessary to give in large amount food which contains the elements necessary to nutrition and which does not cause gastro-intestinal disturbances. Whole lactic acid milk with the addition of glucose, dextrin and maltose, in the form of corn syrup as advocated by Marriott, meets these requirements. High percentages of carbohydrate can be given. It is not necessary usually to remove the fat. These babies begin to gain as soon as the caloric intake is sufficient. This is sometimes 200 or more calories per kilogram.

Interpretation of Bacteriologic Evidence in Influenza and Infections of Unknown Origin

DR. R. A. KINSELLA, St. Louis: The variety of reports published on the bacteriology of epidemic influenza leads to doubt as to the validity of our usual methods of investigating causes of infection. Furthermore, we are disturbed by the reflection that perhaps many of the bacteriologic reports bearing on the cause of infectious processes are fallacious. Obviously, there is need of adopting a central fundamental principle about which our studies can revolve. Such a principle is offered in the consideration that native bacteria, being both adaptable and adapted to their surroundings, do not cause epidemics. Conversely, the bacteria that cause epidemics cannot be those that are common inhabitants of human bodies, but must be unadapted and unadaptable invaders. This principle is effectively illustrated by contrasting adapted and unadapted members of the same group: namely, colon bacilli with typhoid bacilli; Group IV pneumococci with Group I pneumococci; diphtheroid bacilli with diphtheria bacilli, and green streptococci with hemolytic streptococci. Following such a principle, we shall not be misled into ascribing the etiology of influenza to such common varieties as green streptococci and the Pfeiffer bacillus. An analogous situation exists in the study of the so-called streptococcus infections. There is no doubt about the virulence of the hemolytic variety, or about its contagiousness. But we cannot intelligently attach etiologic importance to such ever-present, adapted bacteria as the green streptococci, when considering highly individualized disease processes. Such bacteria as green streptococci and Pfeiffer bacilli depend for their invading activities on a profound local lowering of resistance.

A Plea for a State General Hospital Articulated with County General and Other Hospitals, and the Completion of Medical Education in the University of Missouri

DR. FRANK G. NIFONG, Columbia: Modern medicine and the hospital idea in medical service are inseparable. Hospital and health service is one of the functions of the state for the promotion of the general welfare and it is also the business of the local communities and counties. This matter is not second in importance to education. The county general hospital is a crying need for our more populous counties, no less needed than in our cities. The obligation of the state to give its citizens higher and technical education is a well established principle. The general welfare can be promoted in no better way than by furnishing the best possible medical education to its citizens. We need a great medical center in Missouri University both for undergraduate and for graduate work. The medical department of the university should cooperate with the state board of health in all its activities. To accomplish the various purposes, the state medical department must have adequate clinics and hospitals. A state general hospital articulated with various county and other standardized hospitals would furnish exceptional and unique clinical facilities. This would bring all the people and profession of the state into intimate touch with all health matters and health service.

- *Experimental Production of Edema as Related to Protein Deficiency. E. A. Kohman, Chicago.—p. 378.

Dye Blood Volume Method.—A method is outlined by Smith in which the dye blood-volume method is adapted to repeated determinations on the same animal at short intervals. The soundness of the method is demonstrated by controls done in vitro as well as repeated determinations performed in rapid succession on the same animal. The experimental error does not exceed 5 per cent. Fluctuations in blood volume greater than this are sometimes seen over long periods of time. These fluctuations arise from physiologic factors, the exact nature of which is not yet understood. The dye used is brilliant vital red.

Blood Volume Determinations After Injection of Certain Colloids into Circulation.—McQuarrie and Davis outline a method of determining blood volume which consists essentially in reading refractometrically the serum nonprotein increase after the intravenous injection of a known amount of acacia or gelatin solution, or a mixture of the two. By this method they have found in the dog an average of 9.76 c.c. blood per hundred grams body weight. In the rabbit an average of determinations using samples removed five minutes after injection of medium gives a volume of 6.49 c.c. per hundred grams body weight. Of great importance is the fact that hemolysis, lipemia and cholemia do not affect the accuracy of determinations by this method.

Influence of Splenic Extract on Number of Corpuscles in Circulating Blood.—Downs and Eddy found that the subcutaneous injection of protein-free splenic extract is followed immediately by a decrease in the number of erythrocytes in the circulating blood. The decrease is temporary. The decrease is probably the result of a direct hemolytic action of the splenic agent. The decrease is frequently accompanied by a very transient increase in the number of white corpuscles.

Pathologic Physiology of Acute Phosgen Poisoning.—A study was made by Meek and Eyster of the pathologic physiology of acute phosgen poisoning. The microscope and the roentgen ray both show an early injury to the linings of the deep respiratory passages. Irritation from this results in a certain amount of reflex cardiac inhibition and vasoconstriction. Coincident with these changes there is a direct action of the gas on the red blood cells, which causes them to agglomerate and obstruct the pulmonary capillaries. The removal of red blood cells from the active circulation

in this way results in a decreased hemoglobin percentage. The plugging of the capillaries throws a strain on the right heart and a right-sided cardiac dilatation is apparent. These are the chief characteristics of Stage 1. Even during Stage 1 the injury to the alveolar membranes and the increased pressure have initiated the transfusion of fluid from the blood into the tissue spaces and later into the air passages of the lungs. The rapid development of this edema is the chief characteristic of Stage 2. It results in hemoglobin concentration, reduction in blood volume and decrease in heart size, all three of which proceed to extreme degrees. Death ultimately results from decreased oxygenation of the pulmonary blood and from oxygen starvation of the tissues due to decreased blood volume, the latter, as Underhill states, being probably the more important.

Response of Normal Human Stomach to Vegetables Prepared in Different Ways.—A study was made by the authors of the response of the normal human stomach to thirty different kinds of vegetables prepared in different ways. The evacuation times and acid responses of the stomach were determined and physical and chemical changes in the ingested food noted. In general, raw vegetables low in protein, such as carrots, celery, tomatoes, cabbage, lettuce and cucumbers, leave the stomach rapidly, develop moderately high free acidities but little combined acidity and leave the stomach without great change. Boiled vegetables show much more rapid and complete disintegration. Vegetables high in starch, such as potatoes, show very considerable starch digestion before leaving the stomach. In certain cases hardly any starch reaction could be obtained toward the end of digestion.

Experimental Production of Edema as Related to Protein Deficiency.—The findings obtained by Kohman from experimental study she believes warrant the general conclusion that if it is necessary to limit the amount of protein in a diseased condition or in a period of national economic stress (as was necessary in some of the European countries during the recent war), it is advisable to administer the low protein diet in a form free from excess of water and any acid producing foods. Symptoms of developing edema must be looked for and adequate protein supplied immediately to effect a cure.

- *Severe Case of Gas Bacillus Infection with Recovery. D. S. Adams, Worcester.—p. 373.

Treatment of Intestinal Obstruction.—In the consideration of the treatment of obstruction, Richardson says a distinction should be made between obstruction occurring shortly after operation and obstruction occurring from spontaneous causes, or long enough after operation for adhesions to cicatrize. The place of enterostomy is distinctly different in these two classes of cases. In the first class, its place as an evil occasionally necessary is clear. In the second class, obstruction by recent adhesions, it may be both palliative and curative. Good results depend on operation being undertaken early, and it is far better to operate on an occasional case unnecessarily than to postpone operation until the latter stages of obstruction have developed.

Gas Bacillus Infection and Recovery.—A patient who received a gunshot wound of the leg developed gas gangrene

extending up to his perineum and groin within thirty-six hours. It was rapid in its advance, and yet was controlled by amputation through, and not above, the active process. The case appeared hopeless, but to give the man the benefit of the doubt, Adams performed a guillotine amputation about mid-thigh, with preservation of skin flaps. Dichloramine-T dressings were applied to the raw surface. During the operation 800 c.c. of fresh blood was given, followed by 1,500 c.c. of physiologic sodium chlorid solution containing 2 per cent. sodium bicarbonate. The result was excellent.

Differential Diagnosis Between Tabes and Focal Infection.—Crance cites a case diagnosed as tabes, the patient being treated unsuccessfully for syphilis, in which complete relief from symptoms followed the extraction of abscessed teeth. All the physical signs were suggestive of tabes, but intense antisiphilitic treatment for nine years failed to give relief to the patient. Wassermann tests had always been negative, but the lightning pains were typical. Romberg's sign was slightly positive and there was a suggestion of an ataxic gait. Three weeks after the extraction of all abscessed teeth, the patient was completely relieved of all his symptoms, nor had any of them returned within two months, when he was last seen.

Effects of Alcohol.—While not attempting to say anything good of the use of alcohol as a beverage, Potts endeavors to show that statements of its bad effects on the human race are exaggerated. He also protests against allowing hysteria, hypocrisy and cowardice to influence the settlement of medical questions. It has long seemed to him that if alcohol was nearly as potent a factor in causing mental and physical deterioration as is claimed by many, by this time the world should be peopled almost entirely with physical and mental weaklings. Therefore, the world, instead of progressing as it has, should have gone backward, and the average length of life should be much less in spite of the increase in knowledge and skill in the treatment of disease. Potts believes that most of the indictments of alcohol are based on the results of laboratory work and the study of statistics, and that such evidence is often fallacious and not consistent with actual experience. Potts gives biblical, historical and biographic references to prove his point that alcohol does not cause mental and physical deterioration. Speaking on the effects of alcohol in those who do not use it and do not wish any one else to do so, Potts claims that many such are undoubtedly mentally peculiar. They exhibit a form of bolshevism in that they want to rule or ruin. They alone are right. In furtherance of their views they believe in false statement, vilification, and slander of those who do not agree with them. They refuse to believe conclusive evidence (which according to an old definition means insanity). They advocate confiscation and destruction of legally owned property,

illegal exercise of police power, and they tempt people to do the things they protest against, so that they can show how wicked the world is. Potts is of the opinion that this intolerant exhibition of superiority deliberately shown by this extreme section is based on a form of egoism; it is a consequence of a psychologic self-gratulation and self-esteem which borders on an obsession and is regarded by some authorities as pathologic. The burthen of Potts' paper is summarized as follows: That alcohol is not necessarily a deterrent to good work and to the attainment of greatness; that the world is not going backward in spite of its long continued use of alcohol, and so far as its use is concerned is in no danger of doing so; that every one who uses alcoholic beverages is not per se a drunkard and unable to do his share of the world's work. Potts does not dispute that it may be a cause of harm, both from the medical and social point of view, but it also, from the former point of view, may be an agent for good. He believes that legislation influenced by perversion of facts, hysteria, hypocrisy and cowardice is of more danger to the country than alcohol. There never was a time when common sense was more needed and never a time when it was less prevalent.

Alcohol a Nerve Stimulator.—Clinical observation has convinced Porter that many lives have been saved by the proper use of alcohol. He considered it to be a great mistake to drop so valuable an agent from the pharmacopeia—an agent whose action is so definitely known.

*Garlic as Condiment and Drug. F. del Valle Atilas.—p. 5.
Precautions with Roentgen-Ray Work. J. Barreiro Lago.—p. 10.

Staining Technic for Malaria Plasmodium.—Gutiérrez describes experiences with the different staining methods in vogue to decide which method is the most practicable and reliable. His final conclusion is in favor of the Tiedmann technic, slightly modified. A 1 per cent. solution of methylene blue in methyl alcohol is made, and a similar solution of eosin, and these are kept in dark colored vials. When ready to use, 10 gm. of each solution and 10 gm. of methyl alcohol are mixed, and 10 or 15 drops of the reagent mixture are poured on the smear of blood dried in the air. Then 20 or 30 drops of neutral, filtered water are added immediately, and the slide is tilted to insure the complete blending of the stain and the water. In one and one-half minutes—counting from the moment the stain had been dropped on the specimen—the preparation is rinsed rapidly with water and dried with blotting paper, when it is ready for examination under the microscope. The water used does not have to be distilled water but it must be neutral; he prefers rain water for the purpose. Filtered water from any source can be used, provided that it is neutral. He tests for this by adding a small amount of pulverized hematoxylin to a test tube containing 100 c.c. of the water and agitating gently. If the water turns yellow, this shows acidity, while a deep violet tint indicates that it is alkaline. A light violet tint indicates that the water is neutral and suitable to use. By adding a few drops of a 1 per cent. solution of sodium bicarbonate to the water and then a little more hematoxylin, comparing the tint with a control tube, the neutral reaction can soon be realized. This staining technic shows up all the forms of the plasmodium of malaria and other parasites of the blood, and it is excellent also for the differential leukocyte count. In conclusion he emphasizes that with this simple and reliable technic any practitioner can examine blood specimens, himself, without expensive equipment or relying on a distant laboratory.

Garlic as a Drug.—Del Valle Atilas discusses the therapeutic effects of garlic as reported in the literature, and urges further study in this line as tradition has long credited *Allium sativa* with medicinal virtues. The records of comparatively recent years show that garlic has been advocated in whooping cough in adults, in tuberculosis, in infantile diarrhea, in typhoid, in treating wasp stings, as a stimulant of secretions and as a vermicide, diuretic, anticatarrhal, etc.

Ventriculography.—Ventriculography has been done by Dandy in more than seventy-five cases. The majority of these patients had hydrocephalus: in many cases ventricular dilation was suspected and the injection of air made the diagnosis certain. In many others, the injection was made in order to determine whether the disease was progressive or stationary, in other words, as a means to determine whether or not operative treatment should be instituted. In many cases, Dandy says, the localization of the growth can easily be determined by signs and symptoms and in such instances he has at present no intention of instituting ventriculography, although he feels that eventually this method may be important in differentiating the type of tumor and determining the kind of operative treatment which is necessary. This possibility is strongly suggested by two of the cases described. Five cases are described, each representing entirely different findings and showing the range of usefulness of this procedure when tumors of the cerebral hemisphere are suspected. In all but one of these, the ventriculogram was the only means by which a positive localization could be made. One tumor occluded a lateral ventricle and dislocated both lateral ventricles. Another tumor altered the size and shape of one lateral ventricle. In a third case a cerebral tumor, though suspected, was eliminated by the hydrocephalus. In a fourth case a unilateral hydrocephalus was demonstrated.

Ureteral Ligation.—Faced with the difficulties of deligating a ureter, such as reopening an abdominal wound and searching for a small tie in a pelvis imbedded with plastic exudate, and the ureter incorporated with the uterine vessels, with the consequent danger of hemorrhage and the possibility of cutting the ureter with a resulting fistula—certainly a much more serious operation than a double nephrostomy—and with the same difficulty attending a ureterovesical anastomosis (with the exception of hemorrhage), Caulk and Fischer are of the firm belief that the safest method of protecting the individual is an immediate double or single nephrostomy. If a woman has undergone a pelvic operation complains of pain in the kidney, which is usually about the third day, and this kidney is found to be enlarged and palpable, not having been so beforehand, such symptoms are highly suggestive of ureteral ligation. If the patient's condition would warrant it, a ureterogram would clinch the diagnosis. It is then for the

surgeon to decide whether it is better for the patient to allow the kidney to die or to try to protect it. The danger of a unilateral nephrostomy should be extremely slight, as it can be done under local anesthesia and certainly quickly under gas.

Toxic Goiter.—Eight cases are cited by Roeder. Of these, three had adenomas which suddenly became very toxic. Five cases of hyperthyroidism had their onset definitely following influenza.

Narcotic Tremor.—Thirty-three cases of narcosis tremor have been studied by Rietz. With two exceptions only, the patients were men. Most of the patients were between the ages of 25 and 40. Neither the hospital records nor the objective examination of the patient has afforded any exact means of determining the factors which may possibly be considered as favoring the appearance of the spasms. Neither the technic used in administering the anesthetic nor the anesthetic seem to make any difference nor does the position of the head, etc. The part of the body on which the operation was performed was irrelevant to the appearance of the tremor. On the hypothesis that narcosis tremor is the result of an abnormal irritation of the brain produced by the anesthetic which is conducted thither by the blood, Rietz has endeavored to overcome this phenomenon. To eliminate, at least for a moment, the influence of the irritated motor centers, during an operation on a boy, aged 16, he pressed, for a few seconds, on the neck in the fossa carotica. The result was evident at once; the narcosis tremor disappeared as by magic. It appeared again, however, when the pressure was removed. Renewed experiments had precisely the same effect. When pressure was again applied for a somewhat longer period (about one-quarter minute), the spasms ceased definitely. Although on some occasions the maneuver had doubtful results or none at all, continued observations still showed that the measure was of value. In the thirty-three cases mentioned the measure was used twenty-nine times; four patients had short spasms which ceased of themselves and did not call for treatment. The other twenty-nine cases fall into three groups as follows: In Group 1, the effect was certain in nineteen cases; in Group 2, the effect was uncertain in five cases; in Group 3 the effect was nil in five cases. In no way does the result vary so far as the degree of unconsciousness is concerned nor does the result bear any relation to the duration of the narcosis. It is easier to apply pressure in this region if one stands at one side of the patient and turns his head over toward the other side. The pressure is applied either with the thumb or the four fingers together.

Wassermann Reaction and Miscarriages.—Goodman found that among 1,320 pregnant women, 87 per cent. were Wassermann negative. Only 6.7 per cent. gave a 4 plus positive reaction, and in 2 per cent. more of the cases, the Wassermann was 3 plus positive. Of the Wassermann negative multiparas, 37 per cent. had suffered one or more miscarriages as compared to 52 per cent. of the 4 plus positive cases. Only one woman among the 1,320 gave a history of having been known to be infected with syphilis, although approximately one woman out of each eleven gave a strongly positive Wassermann reaction, indicating in all probability a syphilitic infection.

Potassium Mercuric Iodid Skin Disinfection.—The results obtained by McKenna and Fisher in their experimental work show conclusively that solutions of potassium mercuric iodid or tincture of iodine in dilutions free from any harmful action, are efficacious in killing bacteria on and in the skin, and, therefore, must be considered as having a definite value in lessening the possibilities of bacterial infection in surgical operations as well as in the treatment of traumatic wounds. These experiments also show that potassium mercuric iodid, in a concentration of 1:100 in acetone, or in 70 per cent. alcoholic solution is more efficient for this purpose than is the official tincture of iodine. The greater penetration of the potassium mercuric iodid in acetone and the more rapid evaporation of this solvent make this solution the most desirable one for use. Furthermore, solutions of this double iodid do not stain, and produce no irritation or blistering of the

skin. In these respects, therefore, potassium mercuric iodid, in a strength of 1 per cent. in 70 per cent. alcohol—or better, in acetone—is preferable to iodine for disinfecting the skin.

Relation Between Ulcer and Arterial Supply of Stomach.

—The investigation reported on by Reeves shows that the anatomic arrangements of the arteries along the lesser curvature of the stomach and throughout the first inch of the duodenum are such that the arteries are predisposed to thrombosis. The plexus of vessels in the submucosa on the lesser curvature is made up of much smaller and longer arteries without as free anastomoses as in other regions of the stomach. The branches from this plexus run a very tortuous course to enter the mucosa. The resistance offered the blood stream is constantly greater and, as a result, the blood current is slower as it enters the small arteries of the mucosa. The submucous plexus of arteries in the first inch of the duodenum is made up of relatively few vessels in comparison with other parts of the duodenum. They are small and do not anastomose freely; they give off branches to the mucosa some of which simulate the gastric type of spiral artery. The rather limited blood supply and the gastric type of artery predispose to thrombosis. Since the vessels are more liable to be occluded by emboli, it is reasonable to suppose that they are an important factor in the production of ulcer by hematogenous infections. Reeves submits the hypothesis that possibly slight deviation from the normal may contribute to peptic ulcer.

Transplanting Uterus in Vesicovaginal Fistula.—In the case reported by Dowman a most extensive vesico-utero-vaginal fistula resulted from the pressure of the child's head. She had been attended by a midwife who had allowed her to remain in labor for six days. A physician was then called and removed a dead child by means of forceps. Following this delivery the patient had a constant dripping of urine from the vagina, and no longer voided in the normal way. On examination, Dowman found complete destruction of almost the entire posterior wall of the bladder. This defect was filled in by making use of the uterus. The uterus was freed from all its attachments and was then placed in an extreme anteverted position so that the posterior wall of the fundus could be utilized as the posterior wall of the reconstructed bladder. That part of the bladder wall which was thus accessible through the abdominal opening was sutured to the posterior surface of the uterus by means of chromic catgut sutures, in such a manner as to bring the mucous membrane of the bladder in contact with and approximated to the peritoneal covering of the uterus. The patient was last seen six years after the operation and seemed healthy in all respects. Her bladder had given her no further trouble.

Skin Grafting with Aid of Ethyl Chlorid.—In the method used by Torrance, the thigh is shaved and cleaned with ether and alcohol; and an area on the top of the thigh about the size of a silver dollar is frozen and is cut out with a sharp razor just within the frozen area going well down into the fatty layer. The grafts are applied immediately to the granulation surface and when they become "thawed out" they will be found to be firmly glued to the granulation surface. They very rarely show a tendency to separate if the granulations are in good condition when the grafts are applied and if care is taken not to rub them off. A dry dressing is applied and is changed every day if there is any discharge from the surrounding granulations.

Referred Symptoms in Disease of Gallbladder and Appendix.—The question how morbid changes in the gallbladder and appendix induce symptoms in other viscera and distant parts is gone into to some length by Rolleston, although nothing new is brought forward. The various mechanisms that may be at work in different cases are tabulated as (1) reflex, (2) mechanical, (3) toxic and (4) infective. Reflex: Irritation in the appendix or gallbladder may cause hypertonus of the stomach and spasm of, or failure to relax on the part of, the pyloric or ileocecal sphincter, leading to gastric or ileal stasis and so to excess of acid or to toxemia. Very often the appendix when removed shows little macroscopic change to correspond with the prominent symptoms that then disappear; microscopic examination may be necessary to reveal the evidence of past inflammation in its walls, especially fibrosis in the submucous coat, and often the changes are very slight. Mechanical: Pericholecystic adhesions may embarrass the movements of the stomach, interfere with the passage of food through the pylorus, or even lead to an hour-glass stomach. Though often the legacy left by cholecystitis, these adhesions may be due to duodenal or gastric ulcer. Periappendicular adhesions may cause intestinal stasis and so toxemia, and the same result, only in a more marked degree, may be produced by an appendix adherent across the lower part of the ileum. Toxic: Absorption of bacterial toxins from the gallbladder or appendix may set up general toxemia, cause myocarditis, and damage the mucous membrane of the stomach and intestines, thus giving rise to hemorrhage. Infective: Micro-organisms from the appendix or gallbladder may infect the kidneys, especially the right. Infection of the gallbladder is prone to spread to the pancreas, and local thrombophlebitis of branches of the iliac veins, secondary to appendicitis, may give rise to small pulmonary emboli and pleurisy; malignant endocarditis has been found to be associated with gallbladder infection and with appendicitis. The differential diagnosis of appendix and gallbladder dyspepsia from gastric and duodenal ulcer presents considerable difficulties, but roentgen-ray bismuth or barium meal may give valuable assistance in differentiation. Other conditions mentioned as being caused by disease of the gallbladder and appendix are: chronic colitis; glycosuria and diabetes; cardiac symptoms; pyelitis and pyelonephritis; synovitis and arthritis.

Cancer of Uterus and Pregnancy.—Figures quoted by Spencer indicate that in the child-bearing period of life cancer not combined with pregnancy is at its maximum in patients over 40, but when combined with pregnancy, under 40; and that below 30 the frequency of cancer is six times as great in the pregnant as in the nonpregnant. Spencer's youngest patient was 26 years of age. He has had ten cases in all. Three patients are alive twenty-five, twenty-two and nineteen years after operation, respectively. Each one of the ten patients was a multipara.

Skin Symptoms in Branchial Fistula.—Falling of the hair of the scalp and eyebrows, some loss of eyelashes, skin dry and rather scaly were the cutaneous symptoms in Eddowes' case of branchial fistula. The patient's grandmother had a similar condition.

Treatment of Fracture of Mandible.—Guy maintains that in the vast majority of cases of fractured mandible, immobilization is not only not necessary, but inadvisable, or even prejudicial to a successful issue. The aim of treatment should be reestablishment of function at the earliest possible moment. It is of importance that the fracture should at the termination of treatment be united; it is of still greater importance that the patient should have a lower jaw which is functional, which, in short, he can use. Immobilization in many instances defeats the attainment of this result.

Heat Hyperpyrexia.—Cases of illness due to exposure to high atmospheric temperature are analyzed by Willcox. The clinical types were: (1) heat exhaustion (mild type); (2) gastric type; (3) choleraic or gastro-intestinal type; (4) heat hyperpyrexia (sunstroke). In types 1, 2 and 3 heat hyperpyrexia may suddenly develop unless great care be taken in the removal of patients from a hot atmosphere. Types 2, 3 and 4 are all dangerous, and in them the prognosis is grave. Of eighty severe cases of effects of heat, thirteen (16.2 per cent.) were of the gastric type, nine (11.2 per cent.) of the choleraic, and fifty-eight (72.5 per cent.) were hyperpyrexial. The onset was often quite sudden. Heat hyperpyrexia frequently occurred in the very hot weather in hospital patients suffering from another disease. In them the temperature would often suddenly rise to 110 F., coma and convulsions supervening. Frequency of micturition is a characteristic early symptom, and is sometimes associated with urethral pain. The temperature is somewhat raised, from 100 to 102 F. or so, and the skin is hot and dry. These preliminary symptoms usually last for a few hours, sometimes as long as forty-eight, after which mental excitement and delirium supervene and the temperature rapidly rises to about 110 F. Marked cardiac dilatation, often associated with a systolic murmur, occurs in the severe cases. On examining the urine, indican was found present in excess in all of six acute cases in which a special examination was made. Acetone and diacetic acid were found present in small amount in one out of eight acute cases specially tested. Albumin was detected in small amount in three out of eight acute cases. No casts were seen. Of nervous symptoms, restlessness and delirium occur with the onset of hyperpyrexia, and are quickly followed by stupor and coma, with incontinence of urine and feces. Muscular twitching and convulsions are very common with the high temperature. The knee-jerk is almost always absent in the pure heat-stroke cases during the acute stage. In severe cases the knee-jerk does not return for three or four weeks, in milder cases it returns earlier. The presence of knee-jerks is a valuable prognostic sign, for when they have returned there appears to be much less risk of a relapse, and the patient may then be evacuated with safety. Many of the severe cases after the hyperpyrexia has subsided show a pyrexia, the temperature remaining for several days about 102 or 103 F. For the gastric type of case removal to a cool atmosphere, sodium bicarbonate in frequent full doses by the mouth, and free purgation give the best results. The choleraic type of case is treated on similar lines to cholera. Heat hyperpyrexia demands treatment with sprays of ice-cold water and fans, quinin dihydrochlorid being given intravenously or intramuscularly if there is the slightest suspicion of malaria. Convulsions are treated by venesection, or morphin or chloroform inhalations.

Syphilis in Women.—Skinner presents his analysis of 354 cases of syphilis seen in the course of one year. A few observations are specially emphasized. For instance primary cases are still in a grave minority of admissions. Women do not seek advice in the primary stage, and steps should be taken to disseminate knowledge of the dangers of venereal disease and the advantages of the clinics amongst the female population. Continuity of treatment is essential for cure, and

discontinuity a possible danger. Only where treatment is commenced before the Wassermann reaction has become positive can a cure be definitely promised.

Results of Laryngectomy for Cancer.—Symonds' patients have lived in comfort and happiness, and done useful work for eight, twelve, fifteen and a half, and twenty-two years, respectively. One patient died of old age; here was the most extensive of all the operations.

Tartar Emetic in Guinea-Worm Infections.—Ten cases of guinea-worm infection in various stages were treated by Macfie at Accra by means of intravenous injections of tartar emetic. In five of the ten cases the whole guinea-worm was still in the body at the time when treatment was begun. In two, the sore healed under treatment and the worm did not come away; one of these patients was seen a month and one a week after the cessation of treatment, and appeared to be cured. In one, part of the worm was pulled out and broken off during treatment; this case, nevertheless, did well and was apparently cured. In one the sore closed temporarily, but reopened, and the worm was eventually wound out. One was lost sight of at an early stage. In five of the cases part of the guinea-worm had been pulled out and broken off before treatment was begun; all these cases showed signs of acute inflammation of the affected limb. The inflammation subsided and the guinea-worm sore healed in three of these cases, the portions of the worm which had not been pulled out remaining in the body but causing no inconvenience. One was complicated by the presence of a suppurating wound, so that the effect of treatment was not clear. And one was lost sight of at an early stage. In all but one of the cases treated intravenously injections of tartar emetic, even in the small doses given (3.5 to 9 grams), appeared to have a beneficial action. They appeared to relieve the inflammation caused by the breaking of the worm, to effect the healing of the sore without the previous removal of the worm, and to shorten the duration of the affection. In most of the cases it was impossible to continue the injections as long as had been intended, either because the patients had left Accra or because they themselves had concluded, perhaps prematurely, that they were cured and in no need of further treatment. In the cases which were longest under observation it appeared as if the antimony had killed the guinea-worm in the body and allowed it to be absorbed.

Syphilitic Spondylitis.—The case Evans and Marshall report resembles Fournier's in affecting the same vertebrae, but differs in the absence of cavitation of the vertebrae, abscess formation, and muscular atrophy. The process of new bone formation predominated over bony destruction. This is characteristic of most cases of syphilitic spondylitis and distinguished them from tuberculous disease. Noteworthy features of this case are the rarity of the lesion, its occurrence in spite of treatment, and the persistently negative Wassermann reaction, the first test being made when the vertebral lesions were in active development. This case would therefore appear to serve as a warning against placing too much reliance on the Wassermann reaction, both as regards diagnosis and prognosis.

*Case of Rupture of Bladder. L. Gordon.—p. 72.
Case of Convulsions in a Child, Lasting 24 Hours and Terminating Fatally. C. Sand.—p. 73.

Traumatic Rupture of Bladder.—An unusual feature in Gordon's case, one of traumatic intraperitoneal rupture of the bladder was the obtaining of urine in considerable quan-

tities after catheterizing the patient. The patient had been kicked on the lower abdomen. The house surgeon, suspecting an injury to the bladder, passed a catheter and obtained about 10 ounces of blood-stained urine. Eight hours later 16 ounces of urine were drawn off. The bladder was washed out with boric solution, the amount of solution returned being apparently the same in quantity as was injected. About thirty-six hours later Gordon saw the patient. He suspected an intraperitoneal rupture of the bladder, but as the chief sign in these cases, that with the inability to urinate no urine is obtained on catheterization, was absent, the diagnosis seemed unlikely; still, it was made, and it appeared probable there was a laceration involving the inner coats chiefly with a small leak setting up peritoneal irritation. On opening the abdomen, the peritoneal cavity was found to contain urine, and a large tear the size of a half-crown piece, circular and ragged in outline, was discovered on the posterior wall of the bladder, an inch above the trigone, immediately behind and in line with the urethra. The bladder contained no urine. The conclusion was that on each occasion the catheter had been passed, the point had passed through the rent in the bladder wall and had tapped the urine from the peritoneal cavity. The laceration was closed. The point which seems emphasized in this case is that the possibility of a rupture of the bladder when urine is returned in large quantities after a catheter is passed must not be ignored, and further, that the diagnostic method of injecting a measured quantity of fluid into the bladder and observing the quantity returned cannot always give helpful information.

Kidney Functioning During Fever.—Etienne and Druetne found an unusually low ureosecretory index by the Ambard formula in 43 febrile patients with pneumonia, typhoid, acute rheumatism, tuberculosis or other disease. The output of urine was satisfactory and the kidneys were presumably normal in all but 5. The Ambard constant was within normal range only in 6, but in the 5 with diseased kidneys, the constant was much above the normal. With sound kidneys, the urea content of the blood was normal. These and other findings testify that the fever whips up the kidneys to extra functioning, just as it whips up the heart and the lungs to a more rapid rate. The acceleration of the heart beat drives the blood faster through the kidneys, and they eliminate waste faster and more thoroughly as long as they are adequate to the task. When they fail, or when the kidneys become too congested to keep up the work, then the Ambard constant runs up. Their figures show that the fever may whip up the kidneys to accomplish 200 per cent. of their former work.

The Schick Diphtherin Reaction.—Renault reports application of the Schick test to 281 children during a recent epidemic of diphtheria. None of those giving a negative reaction contracted the disease. Those with a positive reaction did not always develop the disease, even when diphtheria bacilli were found in the throat. The Schick test does not preclude the search for carriers, as children in both the positive and negative groups may be carriers.

March 6, 1920, 34, No. 13

- The Humoral Reactions with Vaccination and Their Connection with Allergy. P. Gastinel.—p. 219.

Confusional Mental States.—This entire issue of the *Bulletin* is devoted to this subject. The first article describes the toxic-infectious types. Headache is the capital symptom; insomnia, tremor, contractures, digestive and urinary dis-

turbance and low blood pressure are also suggestive. Juqueliér discusses posttraumatic mental confusion. Usually it entails gaps in the memory and grooves in the nails showing the nutritional upset. Marchand and Barbé discuss confusional states in relation to psychoses, neuroses and organic disease of the nervous system. Roubinovitch and Dupouy review the field of treatment with special regard to the heart and the general condition, and organotherapy as indicated. Experiments on cats have demonstrated the gravity of thyroid insufficiency in gravid animals, and this is confirmed by the benefit from thyroid treatment in pregnancy disturbances. It may be useful also as preliminary to ovarian treatment at the menopause, at puberty and during lactation. Symptomatic measures alone are not enough; the cause of the confusional condition must be discovered, and during convalescence psychotherapy is indispensable to aid in restoring mental balance.

Bulletins de la Société Médicale des Hôpitaux, Paris

Jan. 30, 1920, 44, No. 4

- Myoclonic Epidemic Encephalitis. Sicard and Kudelski.—p. 121; Idem with Paresis.—p. 123.
*Ascending Myoclonus. P. Carnot and C. Gardin.—p. 125.
*Paget's Disease of Bone. De Massary and Lechelle.—p. 134.
*Congenital Cyanosis. Variot and Bouquier.—p. 137.

Primary Tricuspid Endocarditis. Rémond and Minvielle.—p. 158.
Amyotrophy with Abnormal Course. A. Rémond.—p. 159.

Ascending Myoclonia.—Carnot and Gardin found lesions in the nerve cells of the cortex and medulla and thrombosis of the veins in the meninges at necropsy of a young man who died the seventeenth day after the onset of ascending paramyoclonus. It started in the legs and spread up to the abdomen, arms and face, with fever and delirium. They also report a case of acute chorea in a young woman, five months pregnant, with a purpuric eruption and slight fever, with death in less than a week. They do not know how to class these two cases, but incline to label them influenza. Oettinger recalled that during the 1889-1890 epidemic of influenza, Leyden and Guttman reported some cases with narcolepsy (*schlafsucht*) with a fatal outcome in some of the cases. In the discussion that followed, Sainton recalled Dubini's description in 1846 of what he called electric chorea. The description fits some of these cases of epidemic encephalitis. The jerking of the muscles, he said, is like that from an electric current, and it may be accompanied with paralysis or atony of the muscles innervated by the radialis. In Dubini's description of his thirty-six cases of epidemic electric chorea, there is no reference to any other forms characterized by somnolency.

Paget's Disease of the Bone.—The disease was restricted to one femur and developed at the age of 45.

Congenital Cyanosis.—Variot and Bouquier state that within a recent ten days four newly born infants with congenital cyanosis died when they were from 10 to 15 days old, and necropsy showed a widely patent arterial canal with congestion of the lungs and emphysema, as with death from asphyxia.

Spontaneous Rupture of Abdominal Aorta.—The rupture occurred in consequence of acute insufficiency of the kidney in a syphilitic man of 32, after recovery from a long suppurating war wound compelling amputation.

Herpes Zoster of the Ear.—The herpes zoster involved the outer ear and front part of the tongue, and there were also facial paralysis and deafness—the whole forming what may be called the syndrome of the geniculate ganglion.

Polyglandular Syndrome with Tardy Epilepsy.—Etienne and Richard report a third case in which symptoms of endocrine insufficiency accompanied epilepsy developing after 20 or 30, and in which notable improvement was realized under thyroid plus ovarian treatment. The seizures stopped at once after this organotherapy was begun and pushed, although there were certain equivalents at each menstrual period for two or three months. The phenomena in the case confirmed

the assumption that the brain disturbance was of vascular origin, spasm of the arteries explaining the symptoms, and this could be traced to insufficient functioning of both the thyroid and ovaries.

Subarachnoid Meningeal Hemorrhage.—In one of three cases described—all in young men—no cause for the sudden meningeal hemorrhage could be discovered, and after blood had been released by lumbar puncture, recovery was complete in two weeks. In the second case the hemorrhage followed the pulling of several teeth. The third case was diagnosed as uremia with convulsions, as the urine contained albumin. But lumbar puncture revealed the hemorrhage. Complete recovery followed in each case. The writers warn that too much fluid must not be released at one time by lumbar puncture, or the hemorrhage may be started anew.

*Resection of Scapula in Treatment of Fistulas. Bosquette.—p. 527.
*Causalgia. R. Leriche.—p. 531.

Volvulus of the Sigmoid Flexure.—As the preferable treatment for volvulus of the sigmoid flexure, Ingebrigtsen recommends resection of the loop as this, he says, is the only means to prevent recurrence. If the intestine is no longer viable, resection is the only recourse. Resection in two stages is the procedure recommended if the intestine has not sufficient vitality for an operation at one sitting, for in that case the general condition of the patient will be bad. As the first step, an artificial anus is made, which is closed later. This is done even though the sigmoid flexure does not show signs of gangrene. Primary enterorrhaphy follows the resection if the general condition of the patient permits.

Clinical Notes on Traumatic Shock.—Bosquette and Moulouquet confess to their inability to explain the origin of shock, but they have reached some definite conclusions in regard to it. They regard shock as a morbid entity. Its evolution is independent of the nature of the wounds received, and also of infectious complications and surgical intervention. When it passes off, the change is brought about suddenly and is not ordinarily associated with any event in the history of the case nor with any form of medication. The prognosis in shock cases is less favorable if a tourniquet has been applied for a long time, but there is no evident relation between the type of wound and the shock that may or may not accompany it: both legs may be crushed without any sign of shock. It seems as if there must be some individual predisposition to shock as the intangible factor common to so many unlike cases.

Delbet Treatment of Recent Fractures of Neck of Femur.—Santy, desiring to try Delbet's method of treating fractures of the neck of the femur (which consists essentially in first reducing the fracture as perfectly as possible and then passing a metal screw through the greater trochanter and lengthwise through the neck into the head of the femur), but not having at hand the special instruments recommended by Delbet, decided to use such simple tools as he had at hand. With these he was able to perform the operation in a satisfactory manner. He describes his simplified technic, thinking thus to encourage others who are not supplied with special instruments to try the Delbet method. He bored the hole for the screw with an ordinary gimlet, 10 cm. long,

and used an ordinary screw from 8 to 10 cm. long and 6 mm. average diameter. He gives roentgenograms from seven cases.

Pseudocoxalgia in Relation to Phimosi.—Confirming the conclusions of Adams (*THE JOURNAL*, June 4, 1887, p. 631) and Reverdin, Veyrassat cites a case of his own to show that intermittent coxalgia and pseudocoxalgia may be associated with phimosi, and that circumcision will relieve the trouble, just as it often does hysteria and neurasthenia.

Sudden, Intermittent, Abdominal Migration of the Testicle.—Murard reports what he regards as a rare case of migration of the testicle; in fact, he has been able to find in the literature only one analogous case, that of Sébilleau and Descomps. A boy, aged 14, after a hard day's work, although characterized by no violent effort, suddenly felt a severe pain in the region of the left groin. The pain was so severe that he almost lost consciousness. Then he noticed that the left testicle had disappeared. After five days it reappeared in place, and this was accompanied by the same severe pain as before. This continued to occur about every month, the testicle remaining away for about five days. Sudden and severe pain always accompanied its coming and going. The patient presented himself at the hospital at the age of 16. The last attack had occurred two weeks previously, but since then the testicle had not reappeared as usual, except for half a day. The testicle could not be palpated and an incision was made lengthwise of the inguinal canal. The cord was in place, but there was no testicle at its extremity. While the palpating finger was searching in vain for the testicle, the traction on the cord caused it to suddenly emerge from a sac formed by the vaginalis and peritoneum. The testicle was found to have no ligament attaching it to the scrotum or the neighboring parts. It was of normal size, though it had no epididymis. The vas deferens terminated a little below the inguinal ring. With the idea of attempting an anastomosis, the vas deferens was cut into at three different points, but was found to be impermeable, for which reason it was decided to perform orchidopexy, which was done by the Walther method. Murard left this service two days later, and while he heard a month later that the fixation had held, he is unable to give further details of the end-result.

Umbilical Ecchymosis as a Symptom of Wounds of Liver.—Bonnet reports a case of thoraco-abdominal injury, associated with wounds of the lung and the convex surface of the liver, in which an ecchymosis in the upper half of the umbilicus appeared, as a secondary symptom of the injury of the liver. He offers the case as a contribution to the study of the symptomatic influence of wounds of the convex surface of the liver affecting the suspensory ligament.

Resection of the Scapula in Treatment of Thoracic Fistulas.—Bosquette thinks that partial resection of the scapula should be regarded as the routine treatment in certain cases of thoracic fistula. If a thoracic fistula does not yield readily to treatment, there is a lesion at the base of the tract or there is a foreign body keeping up the suppuration. Accordingly, a cure will be effected by the suppression of the causal lesion if the walls of the tract are not so rigid and immobile as to prevent approximation. In the latter case Bosquette recommends resection of the scapula as very efficacious and points out two advantages of the method: it suppresses a rigid portion of the wall which maintains a dead space and constant suppuration, and, furthermore, it furnishes in the muscle and periosteum strips that are thereby liberated, very useful plastic material for the filling in of gaping wounds. There are two principal indications for the resection of the scapula: (1) when it forms the rigid roof of an intercosto-scapular bullet track, and (2) when the scapula extends like a cliff over one of the borders of the fistulous wound and thus prevents the walls of the fistulous tract from coming together.

Causalgia.—Leriche remarks that causalgia was born with the war and is disappearing with it. As Weir Mitchell pointed out, the atrocious pain finally subsides in all cases. Leriche here explains the causes, the mechanism, and the technic for curing this vasomotor disturbance by perivascular sympathectomy, as repeatedly described in these columns.

Motor Disturbances Following Influenza and Epidemic Encephalitis.—Marie and Lévy have encountered since the fall of 1918 a number of cases with involuntary movements, choreiform or rhythmic swaying of the limbs or trunk, or tremor, or masklike expression, or twisting of the trunk interrupting the gait. The patients were all comparatively young, and all but one had passed through a febrile disease, presumably influenza or epidemic encephalitis, from two to two and a half months before. In all, the motor phenomena gradually became attenuated in the course of a year, but never disappeared completely. In one case the slowness and stiffness of motion seem to be increasing. These motor phenomena, they say, do not fit into the frame of any known disease.

Neuralgia After Herpes Zoster.—Sicard explains that lymphocytosis in the spinal fluid is often found after herpes zoster, and it testifies to the reaction on the part of the ganglia, nerve roots and meninges in the region involved, as has been confirmed at necropsy. This segment is the cross-road where the pains meet, and in certain cases the pains pass into a chronic stage, and operative treatment offers the only chance for success. His experiences on the cadaver seem to show that traction to tear out the nerve (Franke), is useless and dangerous; severing the posterior root alone (Guleke), is liable to entail motor paralysis. Sicard prefers excision of the spinal ganglion and resection of the two adjacent posterior and anterior roots. The ligature includes both roots between the dura and the ganglion, and then the ganglion is torn out. This gangliectomy has to be repeated on four segments of roots. This extradural procedure causes comparatively little trauma, and is all under direct inspection. Intradural section of the posterior roots entails loss of spinal fluid. He applied this latter method also in two cases, successfully in one, but the other patient died. In three cases the extradural gangliectomy cured two of the patients immediately, but the pains persisted in the other case. One patient with chronic neuralgia after herpes zoster, involving the ophthalmic and superior maxillary nerves, died after gasserectomy.

The Pilomotor Reflex.—Thomas explains the difference between the goose-flesh reflex and the pilomotor reflex, and their diagnostic importance as evidence of functioning of the sympathetic system.

Treatment of Epilepsy.—Babonneix says "Cherchez l'héredo-syphilis" in epileptics and, on the least suspicion of it, give specific treatment at once, striking hard and fast and perseveringly. "When syphilis is a factor, anything is possible, even the impossible, sometimes."

Motor Signs of Sciatica.—Roussy warns that true sciatica may be accompanied by inability to bend the trunk toward the side of the lesion as the patient stands. Another test is to flex suddenly the foot on the leg, the limb extended to the utmost. As this stretches the nerve and induces pain, the nerve is drawn up, flexing the thigh on the pelvis, the leg at the knee. The sharpest pain with this is felt in the calf or back of the thigh. A similar effect is realized when the

tip of the foot is, twisted inward, a rotation on the anterior posterior axis of the foot. This induces such pain that the patient usually flexes the limb. These three tests have proved instructive in the three years of experience with neuralgia after war wounds involving the sciatic.

Loss of Technical Skill.—To express this, Laignel-Lavastine has coined the term "atechnia," meaning by this loss of the skill acquired by training in any line. It includes aphasia, amusia, apraxia and similar conditions of acquired incapacity.

Arsenic in General Paresis.—Laignel-Lavastine asserts that as paresis is supposed to be incurable, we are justified in attacking it vigorously, but treatment should begin before the phase of actual dementia is reached. He advises arsphenamin treatment to ward it off if the characteristic meningeal reaction is evident four years after the primary infection. The lumbar puncture fluid reveals in this that the individual is a candidate for parietic dementia long before any clinical symptoms become manifest, and vigorous treatment then offers many chances for permanently warding it off.

 Streptococci in War Wounds. P. Pruvost.—p. 159.

Operations in Diaphragm Region.—Schwartz and Quénu give a further illustrated description of what they call a thoraco-phreno-laparotomy, the main features of which were summarized in an abstract on page 1315, Oct. 25, 1919. They expatiate on the ample access it affords to the spleen and to all organs in the hypochondrium, the cardia, ligation of the coronaries, etc.

Epidemic Hemeralopia.—Tricoire encountered 320 cases of night blindness among soldiers. He ascribes it to lack of vitamins, as all the men threw it off promptly under cod liver oil.

Adherent Palate.—Rouget reports three cases of adhesion of the soft palate to the pharynx wall after an operation for adenoids or tonsils. The parents are inclined to incriminate the surgeon, but Rouget presents evidence that inherited syphilis is probably responsible for the postoperative conditions which entailed the synechia. In two of the cases described the Wassermann reaction was positive, and the third child had a brother with iridochoroiditis. Marfan regards inherited syphilis as the cause of adenoids in the majority of cases.

 Angina Pectoris. Chauffard.—p. 83.

Chronic Inflammation of the Omentum.—Aimes emphasizes the importance of seeking for epiploitis in all inflammatory processes in the abdomen. It may even simulate cancer by the debility and emaciation it may induce and the immobility of the inflamed mass. Bakes resected the adherent transverse colon in one case which proved to be merely an inflammatory tumor that had developed around three ligature threads. The posterior aspect of the omentum should be examined at operations, and all damaged portions should be resected.

Care of the Feet.—Roux implanted a piece of fat, about 0.5 cm. thick, under the head of the fifth metatarsal bone through a lateral incision, and thus cured the pains resulting from the lack of the normal cushion of tissues at this point. In another case, after correcting hallux valgus, he implanted a pad of fat under the head of each first metatarsal bone. The fat was taken from the lumbar region. The woman had long been hobbling on account of pains from her feet, but these procedures restored clinically normal conditions persisting during the year to date. He says of high heels that a foot pointing downward from a nearly 4-inch heel forces the big toe into the tip of the shoe, and the foot rests exclusively on the heads of the metatarsal bones. The wearer is thus preparing for herself hallux valgus and pain under the heads of the metatarsal bones, all of which may be aggravated by arthritis, exostosis or bursitis. Correction of these conditions requires an operation and tedious treatment, and the correction persists only if the precautions are taken which should have been taken in the beginning. The various operative methods are analyzed. "Their results demonstrate," he says, "the wisdom of avoiding hallux valgus." The steep streets of his Swiss city seem to be particularly injurious in this respect. He adds that the interned soldiers, "walking with their feet parallel, using all their ten toes, have taught the advantages of the American army shoe. It would be perfect if it were not so ugly—*disgracieux à faire retourner les passants*. . . . By Americanizing the Swiss shoe, planting the feet parallel, and using all the toes in walking, we can ward off flat foot, pain under the heads of the metatarsal bones, hallux valgus, and the surgeon—all at one stroke."

- *Silver Sodium Salvarsan. O. Nägeli.—p. 161.
- *The So-Called Epicondylitis Humeri. J. Dubs.* Cont'd in No. 10, page 187.
- Testing Vision for Railway Service. A. Erb.—p. 169.

Silver Sodium Salvarsan.—Nägeli has injected this drug 800 times and regards it as progress in the treatment of syphilis. The first batch he received induced by-effects of an angioneurotic character more frequently than with neoarsphenamin, but with later batches these disturbances were less pronounced and less frequent.

Epicondylitis Humeri.—Dubs' analysis of the literature and personal experience with nine cases have confirmed that tennis elbow and the Vulliet-Franke epicondylitis humeri are identical. It develops after athletic or industrial use of the elbow or a single trauma of the epicondyle. But, in both conditions, the trouble is in the capsule of the elbow joint, not in the epicondyle itself. The course is usually over several months, refractory to treatment, but final recovery is the rule.

- Gaiter in Relation to Height. H. Hunziker.—p. 209.
- *Epilepsy and Inherited Anosmia. M. Alikhan.—p. 211.

Epidemic Encephalomyelitis.—Stähelin insists that this is the proper name for what is being called lethargic encephalitis, as the pathologic anatomic findings are the same in all cases while the clinical manifestations may differ widely. In some of his seventeen cases the necropsy findings first cleared up the diagnosis, the symptoms having been rudimentary or atypical. In some cases they seemed to indicate cerebral hemorrhage. In four cases the epidemic encephalomyelitis was confirmed by necropsy, but in each it had developed consecutive to influenza, and necropsy revealed accompanying lesions of influenzal pneumonia. From the records to date it seems that about 33 per cent. of the typical severe cases terminate fatally and numerous others are left with chronic sequelae. He does not know of any convincing testimony on treatment with hexamethylenamin, iodine or lumbar puncture, or as to transmission of the disease by direct contact or by carriers.

Reich says that the disease seems to be appearing all over Switzerland and reports ten cases personally studied. Necropsy in one showed besides the typical lesions of the epidemic encephalomyelitis, findings in the lungs such as are typical of the hemorrhagic lobular, influenzal pneumonia. One lad of 17 developed the disease two days after his father.

Anosmia and Epilepsy.—Alikhan gives the tree of a family of thirty members in four generations, eleven of whom have no sense of smell and four very little, while two members of the later generation are epileptics. The anosmia was transmitted through the women, none of the male descendants having married. The transmission occurred the same through the descendants from a second marriage of the great grandmother. This connection between anosmia and epilepsy should suggest study of the hippocampus major in epileptics and in those with anosmia.

- *Glue in Artificial Limbs. A. Landini.—p. 102.
- *The Anatomic Artificial Leg. C. Ghillini.—p. 121.

Arthrodesis of the Shoulder.—The paralysis of the arm, of spinal origin, in the eight months' infant was followed by spontaneous fracture of the humerus about two years later, and the arm hung limp. Serafini describes the operation with two wire sutures which restored the use of the arm to a certain extent, although the humerus is still elastic and frail. Functional use will correct this, it is hoped.

Trauma of Sesamoid Bone of Big Toe.—Serafini has encountered two cases and summarizes from the literature twenty-two cases of alleged fracture and three of lateral dislocation, and refers to the many cases of inflammatory lesions in the sesamoid bone of the big toe. In his own cases the bone had fractured during a long march or from a fall, and a complete cure followed its removal in one case; improvement is progressing in the other under medical measures.

Radial Neuritis.—The girl was healthy until, at 13, right radial paralysis developed, without pain. It subsided under the usual measures in three months, but bluish patches were noticed on the arm afterward for some time. A year later the paralysis returned as also the purpura in the radial territory. No relief was obtained by any measures, and after three months there was intense pain in the upper arm. A large bluish patch ulcerated, and the disturbances kept up until the radial trunk was exposed and adhesions separated, physiologic saline injected around the nerve, and the nerve wrapped in a segment of artery from a dog. A few months

later the paralysis returned, and it has persisted for three years to date. Bacteriologic examination of the blood the second year disclosed a pathogenic hemorrhagic pseudodiphtheria bacillus. This may have been responsible for the apoplectiform neuritis. Reexamination ten months later was negative, and the serum showed no agglutinating power for this bacillus, but guinea-pigs inoculated with it developed hemorrhages in the skin and, in one animal, in the sheath of a nerve. In the course of six years the girl has thus had four attacks of right and three of left radial paralysis, and at present the radial paralysis is bilateral.

Cinematization of the Arm.—Scalone's illustrations show the tunnel in the stump, traversing the whole mass of the muscle. The end of the stump can be flexed and extended with the entire force of the muscles. A rod passed through the tunnel can be swung to and fro, each end able to describe an arc of over 90 degrees, and exerting great force as it moves an instrument to and fro or up and down.

The Rotation Method for Cinematization of the Arm.—Putti slits the end of the stump for nearly 10 cm., separates the bones, and sutures the skin to make two sausage-like prongs of the end of the stump. Objects can be held between these prongs as between two fingers and, by rotating the arm, an object can be turned with considerable force. These natural prongs have proved particularly useful in one case illustrated in which the man had lost not only both hands, but also his eyesight. With his prong stump he can feed himself, etc., and he has trained the other stump so he can palpate and thus read the raised Braille letters. He is thus saved from the necessity of prosthetic appliances. In this case the prong stump can be rotated for very nearly 165 degrees.

The Anatomic Artificial Leg.—Ghillini made the skeleton frame for the leg exactly to correspond to the human skeleton, the wooden femur, tibia and fibula reproducing the natural curves and valgus, with sponge rubber artificial muscles. In the case described, this anatomic leg has given the very best results in functioning and appearance, and Ghillini declares that the prosthetic appliances of the future will certainly be on the basis of anatomy instead of the old system of straight pegs, etc.

The Children of Women Doing Wage-Earning or Piece Work at Home.—Carmagnano's investigations showed more unfavorable conditions for the children of women of this class than for any other industrial workers. He urges that the legal measures to protect prospective and nursing mothers should be applied to this class as well as to factory workers.

Encephalomeningocele.—Versari reviews the literature on hernia of the brain and meningocele, and reports the successful removal of an occipital meningocele which contained an extension of brain tissue. The bottle-fed infant was only 5 days old at the time, and it died a few months later, but had never presented any appreciable nervous disturbances.

*Paraplegia in Malaria. F. Sabatucci.—p. 193.

*Intraspinal Anesthesia. G. Trogu.—p. 198.

*Seasickness. G. Dragotti.—p. 200.

Paraplegia in Malaria.—Sabatucci reports two cases in soldiers. After a period of weakness in the limbs, followed by intermittent claudication and rectovesical sphincter incompetency, a spinal cord "stroke" followed, entailing paraplegia and retention of urine and stools, with bed-sores in one case. The paraplegia was lax at first but finally became spastic and gradually improved under quinin. One still has slight spastic paraparesis and the other the same accompanied by sphincter incontinence. The spinal cord *ictus* developed after a long march or other effort.

General Anesthesia by Intraspinal Route.—Trogu urges the more general adoption in suitable cases of the Schlimgert-Kehrer method of high sacral anesthesia, and of the intraspinal general anesthesia by Riche's lumbar technic. The latter method is particularly useful for long tedious operations on much debilitated patients. In a recent case the patient required a gallstone operation early in convalescence from typhoid. The 8 per cent. solution of procain was injected by the lumbar route, 1 cc. of the procain to each 5 kg. of body weight, a total of 0.095 gm., withdrawing a total of 10 c.c. of spinal fluid, and mixing it with the anesthetic in the syringe as the injection proceeded. The anesthesia was complete up to the thorax, and the suppurating gallbladder with numerous stones was removed without pain or mishap; a large abscess in the margin of the liver was evacuated at the same time.

Seasickness.—Dragotti recalls that all movements of the body liable to sway the lymph in the semicircular canals may induce symptoms like those of seasickness. A cold or hot douche of the ear may not only produce the same symptoms, but may arrest them when they have been brought on by the movement of the ship. Infants escape seasickness as their semicircular canals and the endolymph are not completely developed. Prevention and treatment of seasickness can aim, he says, only to reduce the excitability of the semicircular canal system, as we are unable to prevent the endolymph from being swung about. The bromids therefore, he declares, are the most effectual means in prevention, and strontium bromid irritates the stomach least of the various salts. Small doses are best, 1 gm. three times a day, beginning a week before going on board the ship and keeping it up during the entire voyage. Other sedatives might also be used. The labyrinth in time loses its extreme excitability. The same effect might be realized on land with the revolving chair or other means to train the semicircular canals to bear the swinging of the endolymph without reaction.

Bacteriologic Findings in Epidemic Encephalitis.—Maggiora and his co-workers report that they isolated from the blood in three cases of severe lethargic encephalitis a gram-positive diplococcus which reproduced in guinea-pigs a fatal disease with torpor, paresis and jerking of muscles, and punctiform hemorrhages in the gray matter of the brain. The diplococcus is a facultative anaerobe and passage through animals seemed to enhance its virulence. Bocculari and Panini report the finding of a gram-negative diplococcus in the blood of patients with lethargic encephalitis and from the blood from the heart in one fatal case. Guinea-pigs inoculated with it developed a diffuse diplococcemia.

Recent Progress in Gynecologic Instruments. C. E. Roe.—p. 430.

Relapsing Fever in Peru.—Del Prado relates that epidemics of mixed typhus and relapsing fever have long been known in Peru, although the two diseases have often been confused. It is a current saying that relapsing fever paves the way for typhus. Not until 1917 was the differential diagnosis of relapsing fever made with precision in Peru and the spirochete discovered, and effectual measures of prophylaxis undertaken against it. Del Prado had charge of the campaign against relapsing fever in the two provinces most ravaged by it in 1918. The disease is endemic in the mountainous districts and appears only sporadically in the coast provinces. Some of the principal endemic foci are in cold regions, on the brow of the mountains. The disease spreads thence to the coast. The hemorrhagic forms have been most prevalent in the epidemics of the last two years.

Anatomy in Prehistoric Peru.—Quesada does not agree with those who regard the evidences of trephining found in the tombs of the period of the Incas as testifying to a knowledge of anatomy. The trephining was probably done for some religious rite or purpose and shows no knowledge of anatomy, and neither does the evidence of setting of fractures or embalming of the bodies. But the ancient Indian language has a number of words corresponding to stomach, pharynx, esophagus, liver, gallbladder, bile, pancreas, intestines, peritoneum, heart, etc., but he thinks that they probably were applied only to animals, not to man. At the same time, the numerous portrait heads made of clay showed a knowledge of the superficial anatomy of the face.

Worm Enemy of Mosquitoes.—Bianchi relates that he found that the larvae of mosquitoes disappeared from aquariums and jars when the water contained a certain worm of the planaria genus. In the course of four hours, in one test, six of the planaria specimens devoured a total of 106 larvae, only two extra large ones being left of the 108 that had been placed in the water in small lots during the four hours. The same planaria specimens were then transferred to a jar containing 200 larvae, and in twelve hours no larvae were left alive, the smaller ones having been devoured, and the others eviscerated by the planaria. The author is professor of comparative anatomy and physiology at the University of Buenos Aires.

Biologic Tests for Tuberculosis.—The article describes a number of biologic reactions which can be utilized for the diagnosis and prognosis of tuberculosis, according to Maragliano's biologic method. For example: The normal human serum does not contain lecithin. When it is found in the serum the probabilities are in favor of tuberculosis being responsible for this. Tests for nucleins, albumin, precipitins, toxi-albumins, kinetoxins, thermoprecipitins, immune serum and analysis of the urine, applying the Russo, diazo and Weiss-Moritz tests—all these form a basis of data on which can be built an accurate estimate of the case and its outlook.

*Ochronosis. O. Gross.—p. 249.

Technic for Administering Digitalis.—Krehl remarks that nowadays he scarcely ever meets any case of heart disease of any kind that has not been stuffed with digitalis. It is administered hit or miss, while in his own practice he tries to modify the circulation without giving digitalis unless it is strictly indicated. He has had cases in which the edema subsided without drugs under bed rest alone, even with valvular disease of all kinds, syphilitic myopathies, or cardiac insufficiency from chronic nephritis; it is immaterial whether the pulse is permanently irregular, fast or slow, or whether there are extrasystoles. He never knew strict bed rest fail to benefit when the diet was restricted to 1 or 1.5 liters milk in the twenty-four hours. The amount of milk that can be allowed, the necessity to drop salt, and the length of time these restrictions have to be kept up, gage the severity of the case. And the same individual gage is found in each recurring attack. It is possible, he says, that the Karel cure might prove equally beneficial with rice and fruit, scanty salt and measured water intake being the main principle involved. It has been his experience that the outlook was more favorable the greater the rise in the specific gravity of the urine as diuresis increased. Water may pass off likewise in sweat or be eliminated by the lungs. He urges further study of the factors which modify the insensible perspiration in these cases. If the relief from casting off the excess of water does not restore clinically normal conditions in the circulation, then we have digitalis to fall back on. This seems to increase the amount of blood pumped by the heart per second, besides its influence in improving the strength of the beat. He gives digitalis at once or not according as the patient has been getting digitalis and is suffering much and the circulation is much hampered.

Elimination of Water by the Kidneys.—Siebeck reports experiences which show that when a given amount of water is ingested, its elimination within a given period depends on whether much or little water has been ingested during the preceding period. When used to test kidney functioning, the outcome may be misleading unless it is known whether the tissues are already saturated with water or are avid for

water. The "water drinking test" seems to act not only on the kidneys but on the water economy of the body in general.

Innervation of the Stomach.—Klee devotes nearly forty pages to his research on the vomiting reflex. He studied it in decerebrated cats by stimulation of the vagus in the neck. The act began always with the persistent closure of the pylorus.

Origin of Gallstones.—Anfrecht has sometimes found at necropsies that the bile in the biliary passages contained such numbers of fine blackish concretions that it felt sandy. This and other findings sustain the assumption that with stagnation of bile the pigments in the liver cells may form concretions which may become the nucleus for gallstones.

Ochronosis.—Gross states that cartilage placed in homogenetic acid turns brown exactly as in clinical ochronosis. This throws light on alkaptonuric arthritis, as there seems to be something in normal blood which destroys homogenetic acid, while this substance is lacking in the blood with alkaptonuria.

- Emigration of Physicians to Latin America. Mühlens.—p. 1389.

Combined Treatment of Eclampsia.—Von Jaschke gives a detailed account of his management of eclampsia cases. He begins his treatment with a subcutaneous injection of 0.015 gm. of morphin hydrochlorid. The sick-room is darkened and the patient is carefully protected against all outside noises. After a fifteen minute interval a superficial ether narcosis is instituted, during which the urine is drawn and a digital examination made to determine the condition of the fetus, followed by venesection. Without the narcosis, exploration or the mere use of the catheter might precipitate a convulsion. The urine should be examined for albumin, and the character of the sediment and quantity of the urine should be carefully noted, as the latter has an important bearing on the prognosis and may affect the therapy. If the child is living, the os fully dilated and the head low in the pelvis the narcosis should be deepened and the child extracted with forceps. The birth should not be forced unless the development of the organs in question and the position of the child permit such a procedure without undue risk. The withdrawal of less than 500 c.c. of blood is useless. More than 500 c.c. should not be drawn until it is seen how much blood is lost at delivery. If eclampsia occurs post-partum, which is rare, venesection can be dispensed with provided the patient has lost a half liter or more of blood during the expulsion of the placenta. After venesection the Stroganoff narcotic chloral treatment is instituted. In severe cases with frequent convulsions it is well to give also, subcutaneously or intravenously, 500 c.c. of Ringer's solution (usually two doses in a twenty-four hour period). Throughout the course of the eclampsia he warns to beware of allowing conditions favoring aspiration pneumonia and biting of the tongue. (The Stroganoff method was described in THE JOURNAL, Feb. 12, 1916, p. 530.)

Diabetes Under War Conditions.—Magnus-Levy cites the mortality rate among the civil population of Berlin in support of the now quite generally known fact that diabetes decreased quite perceptibly in Germany during the war period. Before the war, during the 1900-1914 period, there was a gradual increase of mortality from diabetes, the number of deaths, annually, rising from 245 to 444. During the 1915-1918 period, on the other hand, there was an uninterrupted decrease in the annual number of fatal cases down to 202. Before the war, Magnus-Levy had been inclined to ascribe the increase in diabetes of the previous half century to the nerve-racking age of machinery and the rapid pace at which all classes of people lived, as compared with former

years. He has been compelled to change his view, for diabetes has decreased in spite of the fact that the war brought with it a vastly greater strain on the nervous system than was known during peace times. He now thinks that the former increase was due mainly to overeating and the more luxurious mode of living.

Combined Treatment for Lupus.—Freund describes the method of treating lupus that gives the best results of the many that he has tried during his twenty-three years' experience. He has been using this method routinely for some time. If a given case is adapted to this treatment, that is to say, if the focus of the disease is circumscribed and neighboring mucosae are not invaded, the field of operation is cleansed and iodinated and a local anesthetic is applied. Then, at a distance of 1 cm. from the edge of the diseased tissue, a circular incision, the knife held perpendicular, is made in the healthy tissue just deep enough to cut through the layers of skin. The area thus circumscribed is then dissected off in such a manner as to remove all the diseased tissue in the skin and in the underlying tissue layers. Hemorrhage is controlled by compression, torsion and, if need be, by ligatures. The defect is covered with sterile gauze and bandaged. In a day or two the bandage is removed and the defect exposed to an erythema dose of roentgen rays. The raying is continued daily for seven or eight days, six minutes at a time; the tubes of 4-5 Benoist or Bauer hardness; the secondary current 1 milliamper, and the focal distance from the skin, 20 cm. After the irradiation, fresh petrolatum bandages are applied to the wound, which heals promptly in from eight to twenty-six days, according to the size. Freund has applied this treatment in lupus tumidus et exulcerans of the forehead, the eyelids, the nose, the cheeks, neck, ear, chin, heel, back and buttocks, with areas up to 15 cm. in diameter. With one exception (lupus of the heel) excellent cosmetic results were secured.

- Permeability of the Blood Vessels. J. Bauer and Aschner.—p. 1204.
- War in Relation to Paresis. E. Herzog.—p. 1207.

Various Theories in Regard to Death by Scalding.—After a careful study of the phenomena and symptoms in connection with death by scalding, Pfeiffer rejects the shock theory and reaches the conclusion that scalding is only a special type of a large group of pathologic conditions from the action of heat. Autointoxication of the organism by the waste products of protein metabolism is characteristic of the whole group. Whenever, through the destruction of large quantities of body protein, waste products are formed in large quantities and are retained in the system, thus causing the physiologic defensive system to break down; and, for this or other reasons, the circulation is overloaded with protein degenerative products, the now well known and characteristic picture of protein-waste toxicosis is sure to develop. Pfeiffer thinks that this working hypothesis will explain many hitherto obscure pathologic processes besides those from burns.

Microscopic Studies of the Skin.—Schur approves Lombard's method of microscopic study of the skin in the living organism, and suggests some modifications by way of improvement. The technic, as he describes it, is very simple. The portion of the skin to be examined is moistened with a drop of oil or glycerin (Schur prefers liquid petrolatum), whereby it becomes transparent and is thus more readily examined by the naked eye, magnifying glass or microscope. But as the reflex light is often disturbing, Schur recommends that a cover-glass (10 by 10 mm.) be placed over the oiled spot. In this way a picture is obtained that compares favorably with any histologic preparation. Schur follows the custom of making a general survey of the field with the magnifying glass, noting thus quickly the spots that he desires to examine later with the microscope. The light must fall on the object from nearby, at an angle of about 45 degrees. The Osram light is easily attached to the micro-

scope. The difficulties of the examination lie not in the technic, he exclaims, but in the anatomic interpretation of the picture seen, as from lack of experience we scarcely know what we may normally expect to see.

- *Physiology of Ureters and Kidneys. E. Pflaumer.—p. 407.
Bladder Disturbance in Soldiers on Active Service. V. Blum.—p. 449.
Technic for Pyclography. C. Hammesfahr.—p. 452.

Physiology of Ureters and Kidneys.—Pflaumer concludes his report of experiments of different kinds on the urinary apparatus of about 100 dogs under cystoscopic control. A number of physiologic features were thus detected which impressed him with their efficiency for the purpose designed, such as the arrest in secretion of urine when there is stasis in the ureter or distention of the bladder. He remarks that the fact that urine spurts synchronously from both ureter mouths suggests a central control. Mechanical stimulation of the ureter mucosa does not affect its contractions or the secretion of urine. With a pressure on the kidney of 60 mm. mercury, the secretion of urine is arrested, but change of position has an immediate effect on production of urine. The erect position reduces it, while raising the pelvis increases it.

His results encourage raising of the pelvis in treatment of oliguria, as it facilitates the outflow from the veins and thus promotes production of urine. Another practical lesson from his data is that the polyuria sometimes observed with retention of urine from hypertrophy of the prostate, etc., is not of reflex origin but is a sign that normal conditions no longer prevail in the kidney, as otherwise the stasis in the bladder would check urine production. The polyuria is thus an early sign of kidney disease and warns to clear away at once the obstruction to the flow of urine.

- *Treatment of Harelip. R. Drachter.—p. 194.
*Marking Site for Incision. E. König.—p. 197.
To Reduce Pain with Local Anesthesia. O. Stracker.—p. 199.

Correction of Harelip Apart from the Median Line.—Drahter's illustrations show how he cuts a diamond out of the upper lip, the side angles at the junction of the red lip with the skin on each side. The angles left by excision of the diamond must be about 150 or 160 degrees. The raw edges are drawn together and sutured, the lip flaps meeting evenly. He operates under local anesthesia, and waits until the child is several months old, but the operation can be successfully done when the infant is only 6 or 8 weeks old if in good condition otherwise. The child should not be weaned for the purpose. No dressing is necessary after the suture.

Marking the Site for the Incision Beforehand.—König mentions among the advantages of the practice that the operator does not have to palpate anew for the guiding points after he has disinfected his hands for the operation. It is also a great help in plastic operations to decide the exact path for the knife. Another advantage is that the changes in the tissues from local anesthesia will not mislead as to the location of the gland or tumor below.

- *Sign of Impending Parturition. Momm.—p. 233.
*Spinal Cord Tumors in the Pregnant. C. Meyer.—p. 238.
*Construction of Artificial Vagina. H. Brossmann.—p. 240.

Sign of Impending Parturition.—Momm states that the decrease in weight of pregnant women on the third from the last day of pregnancy, considered along with other data, will often be found a useful means for determining approximately the completion of term. From the two hundred and seventy-first to the two hundred and seventy-eighth day of pregnancy the weight of the patient increases regularly and quite uniformly, the daily increase averaging 56 gm. Beginning with the third day from the last, up till the onset of labor, there

is a sharp decline in weight; during the last forty-eight hours the patient loses 690 gm. on an average. He tabulates the weight findings in the last ten days, day by day, in twenty women. In every instance, the sudden drop in the weight was followed by the onset of labor in two or three days.

Spinal Cord Tumors in the Pregnant.—Meyer gives a case report of a sarcoma involving the spinal cord, first noticed early in the pregnancy, and emphasizes the necessity for the differential diagnosis as operative removal may ward off danger. Otherwise, spinal cord tumors are liable to be mistaken for myelitis and allowed to progress to a fatal outcome, or they may be classed as pregnancy toxicoses not treated early enough by interruption of the pregnancy.

Construction of Artificial Vagina.—Brossmann gives an account of two cases in which he made an artificial vagina. Both operations were successful. In the first case he used the Baldwin-method, as it appeared simpler, and because in most of the cases described in the literature the Baldwin method had been used. In the second case he used the Schubert method and found it more satisfactory. With the Baldwin operation, there seemed to be danger of gangrene in the sutured intestinal loop, followed by septic peritonitis, as described by Guggisberg and Pitka. With the Schubert operation, laparotomy was dispensed with, and the whole operation took place outside the peritoneum; furthermore, the newly formed vagina was more spacious. The only danger that he could see in the Schubert method was that if the sigmoid flexure should, in a given case, be too short and the proximal end of the rectum could not be drawn down to the sphincter without undue stretching, gangrene at the end of the rectum might supervene. It might be well to avoid such a contingency by assuring oneself of the condition of the sigmoid flexure in advance by digital examination.

*The Neck Reflex in Prognosis. D. J. Jonkhoff.—p. 307.
Case of Aplasia of Female Genitals. J. G. de Graaff.—p. 309.

Prophylaxis of Diabetes.—Hoogslag relates that during the period when the populace of the Hague was on war rations, 600 diabetics applied for cards entitling them to certain privileges in the rationing. He assumes that this proportion of 600 diabetics in a population of 350,000 probably extends throughout the country. If this is the case, there are 11,000 diabetics among the total 6,500,000 inhabitants of the Netherlands. He calculates further that these 11,000 diabetics average daily 25,000 liters of urine, with an average of 2 per cent. of sugar. This totals 500 kg. of sugar, and, he declares, a loss of this amount of sugar every day cannot be regarded with indifference these days. The loss in earning capacity and the personal sufferings of the diabetics render it imperative to keep them in the most favorable possible condition. Statistics confirm the increasing prevalence of diabetes, and that the moderate cases with only from 0.5 to 1.5 per cent. sugar, are the ones that in the course of years develop the severer complications. In six recent cases of the kind, the men of 52 to 61 had had from 0.3 to 1 per cent. sugar in the urine for six, eight or twelve years, but paid no heed to the doctor's advice about dieting, as they felt well and strong. Two of them died suddenly in a street car or at a picnic; another developed hemiplegia, bed

sores, and furunculosis, and died in coma; another, gangrene and fatal coma; and another developed headache after a strenuous day, and coma proved fatal the next day. Only one of the group had 4 per cent. sugar, but his robust health persisted for four years, when a furuncle developed in the neck after a local trauma and he died in coma in three days. Several in the group held important positions, and if they had dieted to keep their urine free from sugar, they might have had many more years of useful service. The dietetic restrictions might have become less severe in time, as tolerance is increased by keeping the urine free from sugar. He tabulates the details of the diet which cleared the urine of sugar after an average of 5 per cent. or 2.5 per cent. had long been voided in two cases. In conclusion he urges the family physician to have the urine examined once a year of every member of a family in which there is a diabetic, and he appeals to the life insurance companies to provide for examination once a year of the urine of each policy holder without expense to the latter. Thirty patients have been treated with the Allen-Joslin fasting method, with most encouraging results. He commends Joslin's work to Netherlands physicians, saying, "There can be no question of humbug about it," and adding, "American medical science is taking such excellent advantage of the unlimited financial resources at its disposal that it is to be anticipated that ere long it will become of preeminent importance."

Diphtheria Bacilli Carriers.—Huet declares that the ground is still unstable under our feet in this matter of healthy carriers. They are more common than generally assumed, and how long they can harbor the bacilli is still a question. Twenty children who had been exposed to diphtheria were inoculated with sheep antitoxin, and only one developed diphtheria, but all but four of the others had the bacilli in throat or nose during the following month and two of the children, for two months. By mistake, two smears were taken from one child the twenty-ninth day; the first proved negative, the second positive. Three diphtheria bacilli carriers were found among twenty-five newly admitted inmates of the institution, a sanatorium for children.

The Neck Reflex.—In Jonkhoff's case of status epilepticus the head was twisted to the right and when it was passively turned around to the left, the right arm, which was in extreme extension, became flexed, while the left arm, which had been flexed, straightened out. This neck reflex could be elicited only during the coma. There was also at times a reflex action in the legs and in the eyes from turning the head, but it was inconstant and weak. Necropsy after nine days of coma disclosed extensive hemorrhage in the central convolutions and right ventricle. These neck reflexes were described by Magnus and others, and eight cases have been reported in which they were found in meningitis, hydrocephalus, apoplexy, or idiocy.

Case of Rupture of Spleen. J. F. O. Huese.—p. 401.

Prophylaxis of Venereal Disease.—Van Leeuwen insists that it is necessary to arrange graduate courses on the diagnosis and treatment of venereal diseases, easily accessible to general practitioners. This is important for the early recognition of these diseases and prevention of infection of others. The necessity for ample facilities for treatment is generally recognized, but the importance of persevering in the treatment as long as it is needed must be emphasized more. By cooperation of the national, state and municipal public health services with the sickness insurance companies and enlightenment of the public much can be accomplished, and efforts in all these lines are now under way in the Netherlands. He reiterates that the burden of repressing the spread of venereal disease rests on the general practitioner, with specialists only as consultants, except in the larger medical centers.

The Physician's Duty in Prevention of Venereal Disease.—Van Rijnberk comments on a recent article by van Leenwen in which, while urging the importance of individual preventive measures, and discussing how they should be applied, he had exclaimed: "But I, for my part, shall never regard it as my duty to hold myself in readiness at every hour of the day or night to disinfect any and everyone that applies for this purpose." Van Rijnberk protests that this view is the result of nonmedical considerations. "One might as well refuse to cauterize the wound from the bite of a dog if one knew that the man had been tormenting the dog. What physician would say, 'I do not regard it as my duty to take any steps to ward off rabies from a man that torments dogs.' Wherever danger lurks that the physician can ward off, and he is called on to ward it off, he should never refuse. But he can protect himself against being routed out at all hours of the night, to apply preventive measures, by raising his fees. Those who expose themselves repeatedly to infection will be deterred from applying to him if he charges much for his services, when demanded at untimely hours. But he should give his services whenever they are demanded. It would certainly impress outsiders very strangely to see the physician later welcome and treat the syphilitic patient when, if it had not been for his refusal to apply the preventive measures, the syphilis would not have developed."

Large Families and the Death Rate Among the Children.—Hers records conditions in these lines in a certain district in Holland, giving twenty-one pages of statistics and tables from 1,385 families. They seem to demonstrate that five children is the limit that the mother can bear and rear. The other children in large families die off, from 20 to 50 per cent. dying under the age of 2.

Growth of Children in Summer. K. Zeiner-Henriksen.—p. 262.

Mammary Cancer: Eighty Cases. S. F. Holst.—p. 272.

Erosions in Gastric Mucosa from Stimulation of the Vagus.—Nicolaysen relates that in ten cadavers he found hemorrhagic erosions in the stomach or duodenum or both; in nine, death had occurred from some lesion such as meningitis or chest disease in which the vagus had undoubtedly been irritated. This confirms the results of his research on twenty-five rabbits injected with pilocarpin; they all developed similar erosions in the stomach. Some of the animals displayed marked vagotomy, but the erosions healed rapidly. When the rabbits were given sodium bicarbonate to neutralize the hydrochloric acid, no erosion—that is, no loss of substance—developed in the gastric mucosa. Stimulation of the vagus can thus induce these erosions, but whether they are always due to this is another question.

Bandl's Ring Impedes Delivery.—Brandt describes his third case in which contraction of the lower limit of the contractile portion of the uterus prevented delivery. Only one of the three children escaped with its life.

Acanthosis Nigricans.—There were no papillary growths and the pigmentation subsided after a two months' course in the young man with dementia praecox, otherwise physically sound.

Blood Transfusion in Pernicious Anemia.—Scheel and Bang tabulate the daily findings in regard to the blood and urobilinemia after transfusion of 900 c.c. of blood drawn into 120 c.c. of a 2 per cent. solution of sodium citrate. The patient was a man of 33 with pernicious anemia, his third attack. In two weeks the erythrocytes had increased from 850,000 to 3,118,000; the hemoglobin from 19 to 66 per cent.; the bile pigment in the blood serum had dropped from 45 to 7, and the urobilin figure from 875 (4,500 the second day after the infusion) to 42. The improvement progressed for a time, but the man returned about four months later in his fourth attack, the erythrocytes having dropped to 1,382,000 and the hemoglobin to 28.

CLEARNESS IN MEDICAL SPEECH*

JAMES S. McLESTER, M.D.

BIRMINGHAM, ALA.

When Polonius asked Hamlet, "What do you read, my lord?" Hamlet replied, "Words, words, words." Any one who has served for five years as an officer of this section cannot fail to recall a great deal that was brilliantly conceived and skilfully presented; but if his memory is good he will not have forgotten the occasional paper which, because of its structure and the manner of its presentation, represented to the audience little more than words.

I wonder, then, whether the section will permit, as a sort of swan song, an attempt at constructive criticism on the way in which our work is presented. It must be understood, however, that I dare not offer my own as an example lest I be regarded in the same light as the teacher who advised his pupils that "a preposition is not a good word to end a sentence *with*." I come rather as the man who, though himself no musician, enjoys good music when he hears it.

ESSENTIALS OF A GOOD PAPER

There can be but one valid reason for reading a paper before this section. The author should have something worth hearing. To measure up to this criterion it has been agreed that he must tell of carefully planned original investigation, must be able to establish definitely new facts or principles, or must give such a complete summary in some particular field as will justify deductions of value. And yet, the fulfillment of even these requirements is insufficient to gain for him an appreciative audience; for in addition his material should be presented in a clear, agreeable form, requiring the least degree of effort on the part of his hearers. Unfortunately, we encounter at times papers which are lacking in these particulars. How much better it would be for the high standards of the section if the prospective author, with these requirements constantly before him, would subject his own work to the closest scrutiny.

The writer should be brief. He should bear in mind both in the preparation of his paper and in its presentation that he is being given a hearing before a group of busy men and that time is precious. The time limit for papers is being gradually shortened, for it has been demonstrated that the careful writer can present in a well planned communication an amazing amount of material in a wonderfully brief space of time. This ability can be cultivated. Based on experience as a

listener, I venture to make three pertinent suggestions: Come directly to the point with as few preliminaries as possible; omit every unnecessary detail, and avoid repetition.

He should be able to awaken interest in his subject, else it will be difficult to follow him, his facts will not be widely understood, and his conclusions will soon be forgotten. As an illustration, I have in mind a paper from the pen of a well known physician with an intimate and comprehensive knowledge of his subject, which, because of its rambling paragraphs and poorly constructed sentences, was unconvincing and most difficult to follow. The result was that his ideas were understood by few and remembered by none. A few months later a second paper from the same pen produced quite another effect, the difference being due to the evident care with which this paper was written.

Medical literature, to be followed with sustained interest, requires that we avoid ornateness and superabundance of detail, while striving for unity, proper emphasis, coherence, and clearness of thought.

For the sake then of unity, so often violated, the topic should be limited definitely to such aspects as can be covered clearly within the allotted time; each part should be held to a single point until it is clearly understood, and at the end we should be able to grasp the whole as a single concept. Proper emphasis is served when each part of the communication is spaced according to its value and the whole is given a strong ending. Coherence demands such an orderly sequence of ideas and of paragraphs as will make the entire presentation easy to follow. Clearness in composition depends first of all on clearness in thought, then on precision in the choice of words and care in the construction of sentences and paragraphs. No matter how meritorious the work, it cannot achieve full success unless these principles of English composition are observed.

For fear of being misunderstood, I hesitate to liken the successful medical author to the ad writer, and yet the legitimate aims of the two for a certain distance run parallel. The object of each is to say a great deal in few words, to adhere consistently to the main idea, to emphasize the right point, to hold the reader's interest, and to be readily understood.

We often wonder why the literature of some of our English colleagues is so much more readable than our own. I think I know the reason. Is it not that, having little or no conscience for good English, we do not try? In this connection I might repeat the oft quoted statement that genius is an infinite capacity for taking pains. Careful prevision of composition and paragraphs, and repeated revision of sentences is essential to the production of readable English. It is said that a good writer never ceases to revise his sentences, and

* Chairman's address, read before the Section on Practice of Medicine at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

that the lines which appear easiest are often the result of greatest effort. To go over it all time and again, to see to it that compound sentences are well balanced, to put the important word at the end of the sentence, and to avoid redundancy—this is the price one must pay for a sympathetic hearing and a lasting impression.

A summary embodying the author's conclusions is always of advantage. It enables the audience to grasp in one concept all that has been said; and when the paper is published, it has the additional advantage of telling the busy reader whether or not the article contains the thing for which he seeks.

After the summary has been written, should come the choice of a title. It should be accurate, expressive and brief. It should not be necessary, as is sometimes the case, for the reader to analyze the title with scrutiny in order to determine the real subject.

Even the most carefully prepared paper dealing with the most brilliant work may fail to elicit interest because of the manner of its presentation. Poor enunciation and rapidity of speech are deadly faults; but still more fatal to interest is the speaker who talks into his manuscript rather than to his audience. The custom adopted in the smaller special societies of speaking rather than reading a communication should be encouraged.

Sometimes, too, it is apparent in the reading of a paper that the author is not thoroughly familiar with its contents; he stumbles and hesitates—a thing that can be avoided if he takes sufficient pains beforehand to be certain of what he is going to say and of how he is going to say it. Thorough and intimate familiarity with one's subject creates a certain infectious enthusiasm which cannot fail to enlist the attention of the audience.

Illustrations by means of charts or lantern slides add greatly to the interest of a paper, for, when visualized, a thing becomes easier to grasp and is more readily fixed in the memory. Even here thought and care are necessary, for illustrations should be graphic and well arranged, and every unnecessary detail should be omitted. When it is advisable to include varying details in one table, like data should be included in vertical columns, and each column should be clearly marked. It is a mistake to attempt too much in one chart, for it should be possible to grasp almost at a glance the information conveyed by a single table. Complicated charts that convey a great mass of unrelated facts are difficult to read and should be avoided.

THE DISCUSSIONS

Finally, still in the rôle of critic, may I speak of our discussions? We were taught long ago that we should discuss an individual paper only once; but nothing has ever been said, at least publicly, of the number of times we may with propriety appear on the floor at a single session. However enthusiastic we may be and how genuinely interested in the entire field of medicine, unless we have some pertinent message to convey it would be well to limit ourselves at any one session to a discussion of two or, at most, three papers. It is of advantage to an individual, as well as to his audience, not to speak too often or too much. The audience then is likely to find him more interesting, and his words will carry greater weight.

Again, the suggestion might be offered that the speaker strive to come directly to the point with as little introduction as possible. He should know exactly

what he wishes to say, taking care to omit all extraneous matter, and when he has said it he should quit. We sometimes hear a man who, through embarrassment, doesn't know how to stop, and in seeking a suitable conclusion he repeats over and over again and wanders on. Another man gets half way through a sentence or paragraph and, realizing that it is poor rhetoric or bad grammar, tries to go back and revise it. When once started it is far better as a rule to plunge ahead. Prevision in speaking is good, but revision is impossible.

The object of the discussion, I take it, is not alone to elicit new facts but chiefly to reveal varying points of view. The glimpse we get of the different ways in which these men of varying mental types react toward the same fact is not only interesting but also of much value. It broadens us and helps us to mold our own manner of thinking. In a discussion the speaker should adhere definitely to a consideration of the material presented, and should not attempt to drag into view the far-fetched details of his own work. I recall vividly the instance of a physician whose paper could not be placed on the program, but who was asked to open a discussion dealing with a similar topic. Giving scant consideration to the article just read, he immediately launched into a narration of his own independent studies without attempt at comparison or correlation, and the audience heard, as it were, simply a second paper. The section is naturally interested in hearing a Fellow tell of his own work in its bearing on the subject in hand, but the connection should not be too remote nor the details too elaborate.

The physicians who read papers before this section are in possession of facts and conclusions of infinite importance. How necessary, then, that knowledge of such inestimable value be presented through a medium which is worthy of the subject! A poor lens in a microscope will obscure and distort the object we desire to study; in like manner will imperfections in the expression of our ideas mar and obscure and nullify the thoughts we wish to convey.

930 South Twentieth Street.

TREATMENT OF MALIGNANT TUMORS OF THE ANTRUM*

G. B. NEW, M.D.

ROCHESTER, MINN.

The usual treatment of malignant tumors of the antrum has been the resection of the upper jaw. The results have been operative mortality, very frequent early recurrences, and a small percentage of cures. By the use of the cautery and radium in the treatment of these conditions, I believe that two advances have been accomplished: first, the elimination of an operative mortality, and second, a marked decrease in the percentage of cases showing recurrences. The number of cures in the treatment of these patients by this method cannot yet be determined, but the present results are very encouraging. The cautery has been employed in the treatment of malignant tumors for many years. At the Mayo Clinic for the last three years, malignant tumors of the antrum have been treated by the use

* From the Section on Laryngology, Oral and Plastic Surgery, Mayo Clinic.

* Read before the Southern Section of the American Laryngological, Rhinological and Otolological Society, Cincinnati, Feb. 21, 1920.

of heat in the form of a soldering iron followed by radium treatment, and we believe that the immediate results are much better than when resection of the jaw was performed.

During the two and one-half years from Jan. 1, 1917, to July 1, 1919, thirty-three malignant tumors of the antrum were examined at the Mayo Clinic; fifteen of

of all malignant tumors of the antrum. The figures in Table 2 seem to indicate that almost two thirds of the malignant tumors of the antrum occur in males.

SYMPTOMS

As a rule, the diagnosis of malignancy of the antrum is not made until the condition has become self-evident by the bulging cheek or palate, or the involvement of the floor of the orbit or the nose. The earliest symptom of malignancy of the antrum usually is pain. At first, it may be only a burning or an itching sensation over the cheek due to irritation of the fifth nerve. Later the pain is dull and is frequently referred to the

TABLE 2.—RELATIVE FREQUENCY OF TUMORS IN MALES AND FEMALES

teeth; it is usually relieved when the tumor perforates the wall of the antrum into the mouth or cheek. In some cases, the first complaint is nasal obstruction, and in others the increased nasal discharge brings the patient for an examination. In one of our cases the patient's only complaint was a burning sensation over the cheek. He had no external signs of any neoplasm, nor increased nasal discharge. The antrum was dark on transillumination, and on exploration it was found

Fig. 1.—Water cooled retractor in place on diseased side; soldering iron going in above the alveolar process. The antrum is opened through this route in cases in which the cheek is involved.

this group were so far advanced that we did not believe that any form of treatment would prove of benefit. Eighteen cases were treated by the use of the cauter and radium, although in many of these the lesion was

so extensive that a resection of the jaw would not have been indicated. Since more than half of the patients whom we have examined were treated, the group cannot be called a selected group. The giant-cell tumor and adamantinoma are not included in this list, as they are not true malignant tumors. Of the eighteen cases treated, sixteen were primary tumors of the antrum, and in two the antrum was secondarily involved by a direct extension from the upper jaw.

INCIDENCE OF TYPES OF TUMORS

The data in Table 1 show that squamous-cell epithelioma of the antrum is more than twice as frequent as sarcoma and that it represents more than one half

Fig. 2.—Method of opening into the antrum in cases in which the palate is involved.

to be filled with squamous-cell carcinoma. The nose may be obstructed or the cheek floor of the orbit or palate may bulge as the condition becomes more extensive. Frequently the antrum is irrigated from time to time and later repeatedly curetted until the external signs of malignancy develop, and the diagnosis is made, often when it is too late for radical treatment.

SELECTION OF CASES TO BE TREATED

In the selection of cases to be treated, the type of malignancy as well as the extent of the tumor has to

Fig. 3 (Case 13).—Sarcoma of the left antrum of two and one-half months' duration, in a patient aged 63.

be considered. A rapidly growing lymphosarcoma or round-cell sarcoma may be very extensive and still be treated by the cautery and radium, but it would be hopeless to attempt treatment for a squamous-cell epithelioma of similar size. The age of the patient and the length of the history of the condition are impor-

Fig. 4 (Case 13).—Same patient as in Figure 3 four months after operation. No recurrence after nineteen months.

nancy of the antrum and may be in the parotid, submaxillary or cervical regions: when it is present, the possibility of helping the patient is very slight. No patients with glandular involvement were selected for treatment.

TREATMENT

The usual treatment of malignant disease of the antrum, resection of the upper jaw by means of the Fergusson incision or some modification of this, has not produced a large percentage of cures on account of the difficulty of entirely removing the tumor. The operative mortality, following resection of the jaw, given in the literature from the European clinics, is from 12 to 30 per cent. Kocher,¹ speaking of the results in resection of the upper jaw for malignant tumors, says that recurrence is the rule because removal of all diseased tissue is not certain by our present methods. Schley² says that the average operative mortality of resection of the upper jaw in recent years in America has been from 12 to 13 per cent., that this has been accomplished by almost complete control of sepsis and

Fig. 5 (Case 7).—Fibromyxoma (malignant) of the left antrum, after operation.

hemorrhage, and that pneumonia should be no more frequent after this operation than after the average operation. During the operation for resection of the jaw for malignancy of the antrum, a definite portion of the bone is removed; and usually on account of the bleeding, it is impossible thoroughly to inspect the wound for any pieces of growth that may have been left.

The realization of the value of the use of slow heat in contrast to any cutting operation in malignant disease is by no means new, especially in cases in which it is difficult to determine the exact limits of the growth. The great value of the heat is that it penetrates far beyond the point at which it is applied.

In the treatment of malignant growths of the antrum, the patient is anesthetized with ether by the drop method. The mask is removed after he is asleep. The head of the table is lowered to prevent any secretion in the pharynx from draining into the trachea. A

tant factors. Involvement of the nose and sinuses or floor of the orbit makes the prognosis grave, although it does not exclude the possibility of help from treatment. Glandular involvement occurs late in malig-

mouth gag is inserted on the side opposite the growth, and a water cooled retractor is inserted on the diseased side; a curved retractor holds the tongue out of the way. This gives good exposure and prevents burning the lips or cheeks when the cautery is used. The growth is attacked at the point at which it appears in the mouth, either through the palate or from above the alveolar process (Fig. 1). If the growth has not bulged the cheek or palate, the opening into the antrum is made above the alveolar process, as in the Denker operation. If both the cheek and the palate are involved, a large area of the palate and the jaw is removed with the cautery (Fig. 2). The soldering iron is used as a cautery at a dull heat; a red iron carbonizes and prevents the penetration of heat. The electric cautery has such a large heating element in the handle that it prevents a good view of the cautery point. The soldering iron is carried up gradually into the antrum, and the entire growth is thoroughly cooked for from thirty to forty-five minutes. The limits of the growth

entirely to eradicate the growth at the time of the first treatment by the use of thorough cauterization followed by radium.

Fig. 7 (Case 15).—Postoperative appearance of patient with extensive epithelioma of the left antrum. The left eye was lost from reaction; the glass eye is in place and the cheek is slightly deformed. No recurrence in seventeen months.

Fig. 6 (Case 7).—Postoperative appearance of patient. Note the slight deformity of the left cheek. No recurrence in twenty-eight months.

are known from the clinical examination, and the cautery is used at the location in the antrum cavity at which it is most needed. Since there is practically no bleeding with this treatment, the walls of the antrum may be inspected to determine whether or not the growth has been thoroughly removed. As the patient begins to wake up from the anesthetic, the irons are removed, the mask is applied to the face, and the patient again put to sleep with ether. This may have to be repeated two or three times before the cauterization is completed.

A knowledge of the pathology of the different types of malignancy is essential in determining the treatment. The rapidly growing sarcomas respond well to radium treatment so that it is not so essential that in this group of cases such thorough cauterization be given as is needed in cases of squamous-cell epithelioma of the antrum, which is a most malignant type of tumor. The mixed tumor type of epithelioma or the cylindroma is of rather low grade malignancy and does not require such radical treatment. The aim of the treatment is

Bloodgood³ uses the cautery in the treatment of malignant disease of the jaws and antrum, but recommends that the growth be removed in stages under local or chloroform anesthesia. He attacks the growth through an external incision in the cheek. It has been my experience that it is best to cauterize the growths very radically at the first operation, since this gives the patient the best chance of recovery, rather than removing portions at successive operations. I also believe

Fig. 8 (Case 15).—Postoperative opening into the left antrum.

that the deformity is less and sufficient exposure is obtained by going in through the palate or above the alveolar process than by making an external incision.

3. Bloodgood, J. C.: Treatment of Tumors of the Upper Jaw with the Cautery: A Preliminary Report, *South. M. J.* 12:248-256 (May) 1919.

Ether anesthesia has been employed with no untoward results in these cases.

We have used the radium salts or the emanations in tubes directly introduced into the antrum at the point at which it seemed most needed, either at the time of the operation or from ten days to two weeks later, after some of the slough had cleaned up. We use 100 or 200 mg. for from twelve to twenty-four hours inside the antrum, besides giving radium treatment outside the cheek with screening and distance. The radium is frequently used by means of multiple needles inserted into the wall of the antrum from the inside. The dosage in all cases depends on the type of malignancy, its duration, and extent. The radium treatment may be repeated in three weeks, if indicated. The patients are kept under observation; they return every month or six weeks so that if any recurrence takes place they may have immediate care, since this is very essential in order to control early recurrences. Following the treatment, most of the inside of the antrum comes away as a sequestrum in two months' time, and large openings are left in the palate; but they may be readily closed by prosthetic appliances. There is little inconvenience if the opening has been made above the alveolar process.

RESULTS

Cautery and radium treatment of malignant tumors of the antrum have been followed by no operative mortality and no postoperative chest complications. Two of the patients lost the eye on the side involved from the reaction from the cautery and radium, but in both

three cases, data regarding the present condition of the patient were not obtained. The ten patients who are well cannot yet be considered cured, but their cases should be classified as having been without recurrences for a period of months or years. The results of the

treatment of malignant tumors of the antrum, by the use of the cautery and radium, seem to indicate that the operative mortality that usually accompanies the

cases the floor of the antrum was involved. Of the eighteen patients with malignant tumors of the antrum who were treated, three are dead, two have extensive recurrences, and ten are well and have had no recurrences over a period of from eight to twenty-eight months. In seven of these ten cases, there has been no recurrence after more than one year (Table 3). In

surgical treatment of these conditions has been eliminated, and the immediate results have been improved markedly (Figs. 3 to 10).

THE IMMEDIATE STERILIZATION AND CLOSURE OF CHRONIC INFECTED WOUNDS

A NEW METHOD APPLICABLE TO WOUNDS OF BONES AND SOFT TISSUES *

W. WAYNE BABCOCK, M.D.

PHILADELPHIA

With the mass of the chronic infections of the war, the aim of the Carrel-Dakin treatment—the early closure of the wound—has not been attained. Few of the soft tissue wounds, and I dare say less than 1 per cent. of the thousands of bone infections returned from overseas, have been brought to an aseptic suture. Despite the widespread use of surgical solution of chlorinated soda (Dakin's solution) and the presence of medical officers especially trained in its use, some of our large army hospitals could not up to May 1, 1919, show even a single case of aseptic operative closure for osteomyelitis.

A treatment successful in the hands of highly skilled enthusiasts may fail in routine use when it exacts infinite care as to detail over prolonged periods of time, and when it is adapted only to selected cases and requires repeated operations and multiple and, at times, exceedingly painful dressings. The average surgeon is not constituted to stand on tiptoe all the time, his technic is not invariably perfect, and his soul rebels against the constant infliction of pain. It is not strange, therefore, that he has so often failed in his Carrel-Dakin treatment.

Fig. 1.—Injection of osteomyelitic sinus with saturated solution of zinc chlorid. Gauze is applied to prevent the solution from spurting over bystanders. Forcible injection into sinuses should not be made without protecting the general circulation with a tourniquet. For the pelvis and other bones when a tourniquet cannot be used, the cavity is thoroughly packed with small pledgets of cotton soaked with zinc chlorid.

* From U. S. General Hospital No. 6, Fort McPherson, Atlanta, Ga., Col. T. S. Bratton commanding.

* Owing to lack of space, this article has been abbreviated in THE JOURNAL by the omission of several illustrations. The complete article appears in the reprints, a copy of which may be obtained on application to the author.

We have sought an agent for chronic pyogenic infections that would do rapidly, under adverse conditions and in one operation, what the Carrel-Dakin treatment does so slowly under the most favorable circumstances and with two or more operations. This is the

Fig. 2.—Plan of skin incision for the excision of scar and sinuses. A long incision with free exposure of the bone is essential.

apology for presenting a new method for the immediate disinfection and closure of chronic infected wounds. As to its value in acute infections and against the specific granulomas, we cannot at this time say. We have used the method in closing more than 100 chronic wounds of soft tissue, and in about 250 cases of chronic osteomyelitis.

The soft tissue infections were chiefly granulating areas associated with gunshot injuries of nerves, and the method obviated the necessity of waiting the routine three months after the wound had healed before operating on the damaged nerve. A number of chronic ulcers, some of which previously had been treated by skin grafting, and several infected hernia wounds, also healed primarily after the sterilization, excision and suture. The bone infection cases were unselected, had a variety of infecting micro-organisms, and included the worst cases the ward surgeons could find at Fort McPherson. So far as we know, in only one was the bacterial count below infinity. All had from one to nine sinuses, and had had from two to eight previous operations. Some had multiple sequestrums, complete fracture, associated abscesses, and joint or peritoneal complications. The duration of the disease had been from seven months to more than a year, during part of which time, in most cases, there had been weeks or months of Dakin treatment. A few lacked skin preparation when brought to the operating room, and had purulent crusts, pustules or skin abrasions. It was our desire to determine what results could be obtained under unfavorable conditions.

The osteomyelitis most frequently involved the tibia and femur, but the pelvis, humerus, fibula, radius, tarsus and metatarsus, ribs, clavicle, scapula and mandible were also treated. In two pelvic cases the peri-

toneum was opened, while the hip joint and the knee joint were each invaded five times, from a previously purulent field.

As to the final percentage results, it is too early to speak positively except in regard to soft tissue wounds

Fig. 3.—Freeing of skin and periosteum by retraction with sharp retractors.

which, as a rule, are easily and satisfactorily handled by the method.

With the bone infections, devitalized and insufficient soft tissue, multiple and often closely adjacent scars, complicated sinuses and hemostasis have presented difficulties not found in the usual operation. As a consequence, the operative results could not be judged as after the usual aseptic operation. Tightly sutured wound edges not infrequently showed a limited necrosis. Accumulated secretions from the enormous wound surface often escaped through stitch holes or between sutures. Stitch abscesses and spreading phlegmons were very rare, and usually all openings were closed and the wound firmly healed at the end of six weeks. Of the first 100 cases only four have required reoperation, none of the older healed cases have relapsed, and our present evidence is that a good technician should be able to overcome from 70 to 95 per cent. of his chronic bone infections by a single operation, the percentage varying with the location, extent of the lesion, amount of viable soft tissue remaining, and thoroughness of the operation.

In our 350 cases, there was one death attributable to the operation. This occurred before the danger of injecting zinc chlorid without a tourniquet was appreciated.

TECHNIC

The method consists of four procedures carried out in one operation under anesthesia:

1. Chemical sterilization of all sinuses and wound surfaces by the injection and application of a saturated solution of zinc chlorid.

2. Delineation of infected areas by the injection or application of an alkaline ethereal solution of methylene blue.

3. Mass excision of the entire area of infection.

4. Wound closure with the obliteration of all dead spaces.

Skin Preparation.—If possible, the wound area should be prepared by daily shaving, washing with soap and water, removal of all scabs and crusts, and the application of a 2 per cent. yellow mercuric oxid in zinc oxid ointment for three days preceding the operation. If possible, to reduce the area of skin excised, adjacent skin lesions, pustules, excoriations and eczematous areas should have healed before the operation.

Wound Sterilization.—On the operating table, under local or general anesthesia, the skin is (a) thoroughly scrubbed with "B" solution (compound solution of cresol, 2; turpentine, 10, and gasoline, 88 parts); (b) painted with 3 per cent. solution of tincture of iodine, and (c) sterilized by a saturated solution of zinc chlorid which is thoroughly injected under pressure or packed with small moistened pledgets into all sinuses and cavities, applied to all unhealed and granulating surfaces, and rubbed very carefully over the scar and skin adjacent to the wound. Five minutes are allowed for the penetration of the zinc solution, and great care is taken that every recess of the wound is reached. If injected under pressure, the general circulation must always be protected by a tourniquet. Obviously, the injection will not be made into fistulas connecting with the bladder, intestine or any other important viscus, nor will this method be used in the presence of erysipelas or other acute spreading infection, or before the normal tissue barriers to sepsis have been erected.

Color Delineation.—The antiseptic staining solution, the composition of which is given herewith, is then

Fig. 4.—Removal of diseased bone, sinuses and attached overlying skin and scar en masse. The protection of the skin margins and soft tissues by towels and gauze is not shown.

thoroughly applied to all eroded surfaces and injected under pressure or packed with cotton pledgets into all cavities and sinuses. As soon as this solution has evaporated, the exposed granulating surfaces are left dark blue-black, dry, bloodless on manipulation, and

sterile. If a section is made through the sinus, it will be found that the coloring has penetrated to a depth of from 1 to 3 mm. Outside this is a much wider zone of avascular, grayish white tissue that has been sterilized and devitalized by the zinc chlorid. Some of the sequestrums removed after the treatment from deep bone cavities have produced no growth on culture mediums.

Ether	to make 100

Excision of Infected Area.—The entire field is again painted with tincture of iodine, and a very free skin incision made, so planned as to permit later closure and to surround and be well outside of all scars and sinuses, which are to be excised as near as possible *en bloc*. The instruments are now changed, the skin margins well separated from the adherent underlying tissues by traction with sharp retractors, and dry towels or gauze clipped in position to isolate the wound. The incision is now deepened to the bone, the periosteum is freely incised and retracted from the entire

Fig. 5.—General plan of bone resection, and method of converting pockets, cups, deep gutters and holes in bone into shallow saucer-like defects (semidiagrammatic).

circumference of the bone, protected by towels or gauze, and, beginning some distance from the diseased area, with sharp chisels, the infected bone is freely excised with the attached overlying skin, scars and sinuses. Care is taken not to divide the bone completely, but the healthy medullary cavity should be freely exposed. A blue color indicates that all infected areas have not been removed and that the excision is to be continued. The operator should use very sharp knives, gouges and chisels, and work centripetally from outside the septic focus, rather than with curets, which tempt one to work from within out. If possible, all soft tissues and bone should be removed to a distance of at least 1 cm. beyond the blue coloration.

The bone incisions are so placed as to leave smooth surfaces with no holes, gutters, cups or pockets that will remain as "dead spaces" when the soft tissues are closed, and the incision should leave only well vascularized bone and soft tissue free from bone chips and splinters.

Scars.—As a rule, the scar is excised. If too large, however, for excision it is partially excised and the residual part freed, with as thick a layer as possible of underlying tissue to maintain its nourishment.

Large Bone Defects.—These, especially if near the articular ends, may be filled by pediculated flaps of

muscle or other soft tissue, or lined by large pediculated thick skin flaps. We have found the inward transposition of the head of the tibialis anticus and extensor longus hallucis useful for filling large defects of the head of the tibia. The defects left by removing skin flaps may be closed by plastic operation or skin grafting. In case there is a complete fracture, the bone ends should be beveled to chisel edges, and appro-

Fig. 8.—Massive nontraumatic osteomyelitis of tibia, of one year's duration; four previous operations; bone riddled with sinuses containing pus, sequestrums and exuberant granulations before operation.

priate extension and immobilization should be maintained in the after-treatment.

Multiple Sinuses.—These should be excised if possible. If left, the entire sinus tract will usually later be expelled in the form of a tube of necrotic tissue. To avoid secondary hemorrhage, no zinc infiltrated tract should be left adjacent to a large blood vessel.

Secondary Hematomas.—These are difficult to overcome entirely. Bleeding from bone may be controlled by gauze pressure or by pressing bits of muscle into the bone. Bleeding from soft tissue should carefully be corrected by forcipressure, fine catgut ligatures, or sutures. A lateral stab or incision through an adjacent scar may be left for drainage. Tube drains we have discarded. We have observed no secondary hemorrhage when the method has been accurately followed. In a case in which a surgeon failed to excise and to suture for a treated sinus adjacent to the femoral artery, secondary hemorrhage necessitating ligation occurred on the third day.

Fig. 9.—Lesion shown in Figure 8, five weeks after operation; immediate sterilization, excision, and closure without drainage.

Wound Closure.—The muscles and soft tissues are sufficiently liberated from the skin and bone and each other to fit into the bone defects. If possible, the bone should be covered by a layer of muscle and aponeurosis as well as by skin. Muscles should be well freed and sutured with the edges inverted and rolled in, so as to fill all bone cavities or depressions. Plain catgut sutures are used to unite the deep tissue layers, and

the skin is closed with an everting mattress suture of silkworm gut. Only a dry technic is employed. A sterile 10 per cent. solution of sodium bicarbonate is kept at hand to neutralize the zinc chlorid in case of accident.

After-Treatment.—The early dressings should be copious and should give supporting pressure. Wet, nonirritating, antiseptic dressings are applied for the

first week, and until all tissue reaction has subsided. For this purpose we use Solution "C," which is injected into the gauze dressings through incorporated rubber tubes every two to four hours. The part is well supported, and is kept quiet, elevated and warm.

In the after-dressings, the surgeon should refrain from probing, injecting, milking, squeezing, or introducing tubes or any other thing into the wound. If there is marked distention from retained wound secretion, a stitch may be cut and the wound margins slightly separated. Daily wet dressings should be continued until complete healing has occurred. The adjacent skin is to be kept clean and coated with 2 per cent. yellow mercuric oxid ointment. As with other closed wounds, Dakin's solution is not to be employed. In several of our early cases, union was prevented by its use.

Approximation stitches are removed on the third or fourth day. The patient should not use the part until it is soundly healed and no longer tender. The wounds are usually much less painful than those left open for Dakin treatment. Should a chronic bone sinus form after the operation, thus indicating a technical defect, the operation may be repeated, with the expectation of finding a simplified surgical problem.

Unless the surgeon can prevent the entrance of the zinc chlorid into the general circulation during and for five minutes after the injection, and unless he is able to excise freely all chlorided tissue adjacent to the important structures, he should not employ the method.

2033 Walnut Street.

Home Treatment by Quack Medicines.—If there is anything urgently required in the education of the populace at the present moment, it is that of emphasizing the evil of home treatment by quack medicines. By such practice, skilled advice is withheld and delayed in the beginning of disease, and irreparable harm is the result.—*Medical Press and Circular* 109:66 (Jan. 28) 1920.

GRANULOMA INGUINALE IN THE UNITED STATES

DOUGLAS SYMMERS, M.D.

Director of Laboratories, Bellevue and Allied Hospitals

WITH THE COLLABORATION OF

ALBERT D. FROST, M.D.

Pathologic Intern, Bellevue Hospital

NEW YORK

Granuloma inguinale is a chronic ulcerative lesion of the inguinal region which may involve the external genitals, the perineum, the inner surface of the thighs, the anus, and, in the female, the vagina. According to one view, the infection is of venereal origin; in other quarters it is regarded as an independent disease. The ulcers persist for years, are serpiginous, and may involve extensive areas of skin in direct connection with or independent of the external genital apparatus. In most instances the process shows no tendency to spontaneous healing, although this method of cure is not unknown.

As far as I have been able to learn, so-called granuloma inguinale has not hitherto been recognized as a lesion indigenous to the United States. On the other hand, it is endemic in many tropical countries, and absent in others. Thus, in certain of the West Indian Islands it does not occur at all, while in British Guiana it is widely prevalent. Moreover, it presents different aspects in different races. In negro peoples the manifestations are the most pronounced. When other races, as Indians, become infected in a country where most of the

Fig. 1 (Case 1).—Appearance of the ulcer in granuloma inguinale, showing the irregularly serpiginous outline, the character of the scab and, where this is lost, the dense fibrous base.

sufferers are negroes, the lesion presents recognizable differences in the two nationalities in that the growth in the Indian is less coarsely granular in appearance and tends to remain localized, whereas in the negro it spreads extensively. In the Fiji Islands, the Melanesian immigrants are said to suffer from a disease which, although it resembles the ordinary form of granuloma inguinale, differs from it in that the lesions are softer, more prominent and spread by contact, so that multiple discrete growths arise. In addition, variations in severity depend on the part involved. Thus, growth and destruction are more rapid on mucous than cutaneous surfaces. Finally, there is a variety of granuloma inguinale attended by such marked obstruction to the lymphatics that it produces chronic edema of the vulva, penis or scrotum, resembling elephantiasis.¹

Since, in the tropics, there are many granulomatous formations about which little is known, it is impossible to state with certainty whether the several chronic ulcerative lesions occurring in the region of the

1. Daniels, in Allbutt and Rolleston: *System of Medicine* 2 (Part 2): 708, 1912.

groin and external genitals are manifestations of one and the same process, or anatomically related reactions arising in response to different causative agents, or the result of combined factors. However this may be, there is at least one variety of granuloma inguinale that has been frequently observed and whose clinical features appear to be much the same, no matter in what country they are seen. In this particular variety, cell inclusions were described by Donovan² in 1905 and have since been found in ulcerative lesions of the groin in widely remote parts of the world. These intracellular inclusions have been studied by Walker,³ who regards them as small encapsulated bacilli belonging to the Friedländer group. The evidence that they bear a direct causative relationship to granuloma inguinale, however, appears not to have been definitely established. On the other hand, it has been suggested that the presence of these intracellular bodies is due to secondary infection of venereal or other pudendal lesions and that, once established in the tissues, they dominate the local pathologic process and promote destruction of tissue. At Bellevue Hospital we have recently had occasion to study two chronic ulcerative lesions of the groin occurring in negroes. From the secretions in both cases, intracellular bodies morphologically identical with those described by Donovan were found. One of the cases appeared to represent a typical example of granuloma inguinale as encountered in the tropics. The other, however, was possibly syphilitic in nature.

REPORT OF CASES

CASE 1.—A negro man, aged 29, who was admitted to the Urological Service of Drs. Keyes and Jeck, by whom I was asked to see the patient, stated that he was a native of Georgia and that he had never been outside the United States. Two years previous to admission to Bellevue Hospital, a pustular lesion appeared on the head of the penis. This was soon followed by ulceration and sloughing, which finally involved the skin of the right inguinal region and the corresponding perineum and scrotum. The Wassermann reaction was negative with both the cholesterinized and the crude alcoholic antigens. The ulcerative area was serpiginous in outline and covered by an elevated, dirty brownish scab made up of innumerable nodular masses, many of which showed numbers of superimposed laminae (Fig. 1). Removal of the scab revealed a broad serpentine ulcer extending a few millimeters beneath the surrounding skin. The edges of the ulcer were rather sharply defined, and the base was composed of smooth, dense, light cream colored or whitish tissue which was bathed in thin, slightly cloudy fluid. The scrotum was edematous.

The occurrence in a negro of an extensive serpiginous ulcer of the inguinal region that had been present for two years immediately suggested that the disease belonged in the category of the tropical granulomas. Smears from the secretion,

stained by the method of Gram, confirmed this suspicion in that many of the polymorphonuclear leukocytes revealed intracellular bodies corresponding in all respects to those described by Donovan; that is, micro-organisms of coccoid, diplococcoid or short bacillus-like forms lying in a clearly defined area of vacuolation. In most of the cells these micro-organisms were arranged in clusters; occasionally they were solitary or grouped by twos and threes. In rare instances isolated forms were observed lying between the leukocytes. No capsules were demonstrable by special methods of staining.

A few days after these observations were made, Dr. Juan Iturbe of Caracas, Venezuela, saw the patient, and out of a broad clinical experience with the disease, confirmed the diagnosis of granuloma inguinale, at the same time concurring in the identification of the intracellular inclusions as indistinguishable from those familiarly encountered in the tropics.

A small portion of tissue was removed from the edge of the ulcerating area for microscopic examination. The stratified squamous epithelial covering at the edges of the ulcer was markedly thinned and the epithelial pegs were atrophic. The subepithelial connective tissues were extremely sclerotic and enclosed occasional collections of small round and plasma cells, together with groups of dilated ducts of sweat glands.

The patient died, but no necropsy was obtained.

Fig. 2 (Case 2).—Large ulcer of the head of the penis and of the tissues of the thigh just below the right groin, both ulcers covered by exuberant granulations.

CASE 2.—A negro, aged 26, admitted to Bellevue Hospital, Jan. 13, 1920, and discharged at his own request, February 26, was a native of Pennsylvania, and said that he had never been outside the United States. In February, 1916, he developed a sore on the penis, but no history of secondary symptoms of syphilis could be elicited from him. Two months after the appearance of the penile sore, a pimple appeared on the anterior part of the right thigh, just below the groin. Ulceration soon followed, and in the course of the next two months the lesion stretched completely across the anterior sur-

face of the thigh. The patient came to Bellevue Hospital and was treated by intravenous injections of arsphenamin, and the ulcer in the inguinal region healed. Shortly after he left the hospital, however, the scar broke down and the ulcer soon reached the same proportions as formerly. At the time of the patient's second admission, he presented an ulcerated area involving the head of the penis, together with a large ulcer on the front of the right thigh (Fig. 2). Both ulcers were covered by exuberant granulations. The epitrochlear lymph nodes on both sides were palpable, but otherwise there were no clinically detectable evidences of syphilis. The Wassermann reaction was negative with both antigens (icebox fixation).

The patient was given five intravenous injections of from 0.5 to 0.9 mg. of neo-arsphenamin, mercuric salicylate into the muscles and mixed treatment by mouth. The exuberant granulations in the ulcer on the thigh were curetted away, and at the end of six weeks healing was practically complete, while the ulcerated area on the head of the penis showed marked improvement. The patient left the hospital against advice.

At the time of admission, films were made from the secretions of the ulcers on the penis and thigh, and from both places showed gram-negative inclusions lying in large mononuclear cells and presenting identical morphology with those found in the first case, although not in the same number of cells

2. Donovan: *Indian M. Gaz.* 39: 414, 1905.

3. Walker, E. L.: *J. Med. Res.* 37: 427 (Jan.) 1918.

(Fig. 3). When found, however, they were not to be distinguished from the Donovan bodies of granuloma inguinale, and occurred in the cells either singly or in small groups, occasionally in such large numbers that they could not be counted.

At operation, the curettings were received into sterile dishes, brought to the laboratory, and the tissues were crushed by platinum tipped forceps and emulsified in sterile salt solution. Material from this emulsion was streaked successively on plates of plain agar, blood agar, dextrose and ascitic agar and North's medium, and inoculated in dextrose broth; and although various contaminants were found, no micro-organisms corresponding to any known pathogenic form were grown, nor was any prevailing or constant growth to be recognized in the cultures. Anaerobic cultures were likewise negative. Before operation, bouillon cultures from the ulcer on the thigh yielded similar results. Since *Bacillus mucosus-capsulatus* is readily cultivated by these methods, we assume that the micro-organism obtained by Walker and so identified by him in cultures from granuloma inguinale was probably not present in this case, although in films from the secretions in both cases apparently identical intracellular bodies were found. In other words, the identity of these bodies seems still to remain doubtful, in spite of Walker's valuable work.

Fig. 3 (Case 2).—Pen and pencil sketch of film from secretions of ulcer: At the center is a large mononuclear phagocytic cell enclosing numbers of coccoid, diplococoid or short bacillus-like parasites, each lying in a clear zone of vacuolation (Donovan bodies), and in other parts of the field are polymorphonuclear leukocytes.

Guinea-pigs were inoculated intraperitoneally and rabbits intracutaneously with the emulsion of tissue removed at operation without the slightest evidence of reaction. Microscopic examination of the tissue taken from the patient's thigh showed, at the periphery of the ulcer, a markedly hyperplastic superficial layer of stratified squamous epithelium, beneath which were granulations associated with small round cells and numbers of eosinophils.

COMMENT

Whether or not our second case is to be classified with tropical granuloma inguinale is uncertain. Syphilis and the secondary invasion and phagocytosis of Donovan bodies cannot be denied. It remains, however, for subsequent investigation to show whether these bodies are or are not to be found in ulcerative lesions of different kinds, particularly in the region of the genitals, where it is possible that an open wound and local conditions of heat, moisture, etc., invite the entrance and multiplication of invaders whose presence promotes ulceration and prevents healing. Among

physicians in the tropics, granuloma inguinale is usually accepted as a disease in which these bodies play an important rôle, and the intravenous use of tartar emetic is said to be curative.⁴ It is also said that the same drug is advantageously to be employed in the treatment of such parasitic diseases as bilharziasis, filariasis and leishmaniasis. That the lesions in our second case responded favorably to intensive anti-syphilitic treatment suggests but does not prove the syphilitic nature of the original lesion. On the other hand, it raises the question whether arsenic compounds, if pushed, may not act as effectually in granuloma inguinale as those of antimony, since the two metals belong in the same group, and their physiologic action is in many respects similar. Whatever the intracellular bodies may be, their constant occurrence in certain groin ulcerations in different parts of the world must be of some significance as either initiating or promoting destruction of tissue. Our experience at Bellevue Hospital would appear to establish the fact that lesions similar to or identical with those of granuloma inguinale, as it is seen in the tropics, associated with morphologically indistinguishable intracellular parasitic inclusions, are occasionally to be found in American negroes who have never been exposed to the vicissitudes of tropical life—in short, that the disease is indigenous to the United States.

THE TRIPOD METHOD OF WALKING WITH CRUTCHES

AS APPLICABLE TO PATIENTS WITH COMPLETE
PARALYSIS OF THE LOWER EXTREMITIES

ROBERT W. LOVETT, M.D.

BOSTON

Complete paralysis of both lower extremities is not necessarily a bar to some form of ambulatory activity. This has been repeatedly demonstrated in infantile paralysis, and the same generalization can be extended to similar flaccid paralyses resulting from fracture of the spine or gunshot wounds of the spinal cord. As the latter class of cases has been called to our notice by the war, a consideration of how these patients also may be taught to walk is one object of this paper.

If a cadaver is stood upright on its feet, the knees flex and the body crumples down on the floor. If the knees are held rigid by the application of splints to hold the knees extended, and if the cadaver is steadied in the upright position by the pelvis, the trunk falls forward. Exactly the same thing happens to a patient with flaccid paralysis below the waist. If the knees are prevented from flexing by splints, the erect position can be maintained without crutches only if the gluteus maximus muscles are strong enough to hold the trunk from falling forward, that is, if they can hold the trunk extended on the legs. The two muscles most necessary to maintain the erect position are the quadriceps extensor femoris and the gluteus maximus.

It has been found, in aiding patients with such a distribution of paralysis to walk, that if the knees are kept from flexing by simple splints, the loss of the gluteus maximus can be compensated for by a peculiar method of using the crutches for what may be called "tripod" walking. If the crutches are placed apart

4. Aragão and Vianna: *Memorias do Instituto Oswaldo Cruz* 5: 211, 1913.

and slanted well forward at their lower ends, they form the two anterior points of a tripod, while the third and posterior part of the tripod is formed by the body of the patient inclined forward at its upper part, with the feet well behind. The apex of the tripod thus comes at the shoulder level of the patient, his body and legs forming the posterior support of the tripod, and the crutches the two anterior supports. Such a position is stable because (a) the base of support is a large triangle bounded by the three points of support of the tripod, and (b) the body is stable in the over-extended position because hyperextension of the hips is checked by the "Y" ligament of Bigelow, and, with the knees stiffened by the braces, the center of gravity falls in front of the hip joints and keeps them extended and firm. A paralyzed patient with no power below the waist can stand unsupported easily in this position, provided there are no contraction deformities in hip, knee or ankle.

The patient must next be taught confidence in this position. If he has been long confined to his bed or chair he will in large measure have lost his sense of upright equilibrium, which must be dealt with by itself and restored by repeated practice in standing on crutches with support near at hand, or by standing with both hands resting on the foot rail of the bed. When he has sufficiently acquired the sense of balance to have self-confidence, he should begin on progression. This is accomplished by hitching one crutch a few inches forward, then the other crutch, and then, in cases of complete flaccid paralysis, jerking the feet forward together a few inches by a body movement, bearing down with the hands on the crutch bars and sliding the feet over the floor. If any degree of power remains in the iliopsoas muscles, which is often the case when the gluteus maximus and all muscles below it are paralyzed, the feet can be more easily advanced one at a time, only those patients affected very severely having to slide along both together. Most patients without any power in the hip flexors are able to accomplish this advancing one foot at a time by a twisting of the body.

The one essential in bad cases is that the tripod should have a large base, and the body be sufficiently inclined forward to keep the center of gravity in front of the hips. If it falls behind them the patient will double up backward like a jack-knife on account of flexion of the hips.

For holding the knees extended one uses the Thomas caliper splint, the simplest, lightest and best of all such apparatus. Two uprights, one outside and one inside of the leg, pass from the shoe to just below the gluteal fold. They are shaped to the leg, and at the bottom each is bent to a right angle. The bent parts of

the upright slip into a tube in the heel of the shoe. At the top the uprights are fastened to a posterior, flat, curved band passing just below the gluteal fold, and a fenestrated knee cap of leather holds the knee extended. The splints can be jointed at the knees for greater comfort in sitting, but the joint must be provided with an automatic drop catch which locks when the knee is extended. The use of a pelvic band on the braces rests on no anatomic or mechanical basis and is never necessary.

If much abdominal weakness is present, a cloth corset is advisable to support the abdomen and give greater steadiness.

In flaccid paralysis of the lower extremities it is a fact that any patient of average intelligence, with one good arm and one arm good enough to hold a crutch, can be made to walk, provided deformities of the hip, knee and ankle are not present, or have been corrected. This walking in some cases may be a very imperfect affair, and is of course wholly dependent on apparatus; but it is better than spending one's life in a wheel chair, and many patients with apparently no power of any consequence develop a surprising amount of usefulness.

REPORT OF CASES

CASE 1.—Poliomyelitis.—A woman, aged 29, paralyzed by poliomyelitis in the summer of 1916, was very helpless. In February, 1917, she was furnished with caliper braces and a cloth corset, and her routine in July, 1918, is shown in the following memorandum furnished by her:

"Gets out of bed into chair alone. Gets in and out of bath and dresses without help. Often dresses and gives 3-year-old boy his bath. Also once in a while washes old English sheep dog. Can make beds, dust, etc. Gets downstairs by sitting down on steps, then into chair downstairs without help. Goes into kitchen almost every day and does some cooking. Has done canning and put up preserves and jellies. Has often washed and ironed. Also cleans silver every week. Can get out on porch and out of doors in wheel chair over a little

runway. Has raked and watered the garden a little and planted seeds. Has Red Cross meeting every week and cuts and sews. Can get into almost any chair alone from wheel chair. Goes automobiling a good deal, but has to be helped into machine. Has been away week ends, taking small wheel chair into machine. Walks every day in the house and out of doors a great deal on the grass. Does daily exercises and has frequent massage. Is steadily improving."

CASE 2.—Poliomyelitis.—A man, aged 40 was paralyzed by poliomyelitis in 1908, and up to July, 1917, had never walked, having spent the intervening years in a wheel chair. His paralysis was practically total from the waist down, with involvement of the abdomen and some of the erector spinae muscles. Braces and corsets were applied in November, 1917. In December of that year he wrote: "Friday I walked probably 20 feet, turning around twice. . . . I find that I can walk in the natural way, that is move one foot and one crutch, and then the other foot and the other

Position necessary in tripod walking (Case 5).

crutch." In March and April, 1919, he wrote: "I am now able to get out of my chair without help and get back in the same way. I back the chair against the wall, turn a little on my side, and get on my feet holding on the arm. Then I can straighten up, take my crutches and go on. . . . Have been over three steps with the help of a banister, and can get in and out of an automobile by myself." Subsequently he informed me that he had attended a large dinner at one of the hotels, going in an automobile, taking his crutches, and walking into the hotel across the lobby to the elevator, and in to dinner.

CASE 3.—*Polio-myelitis.*—A boy, aged 11 years, was referred by Dr. Henry Ettinger of New York, and was seen in April, 1917. He had suffered from poliomyelitis in 1911, and was unable to stand or walk for some years on account of a flexion deformity of both hips, holding them at right angles to the body. There existed total paralysis of both legs, including the gluteus muscles, but some degree of hip flexor power persisted, probably in the psoas muscles, which was the cause of the deformity. Abdominal paralysis was nearly complete, and there was weakness of the back muscles. The legs were brought into line with the body by operation (Soutter fasciotomy) in April, 1917, and by September the boy could walk in the manner described. He can now walk indefinitely on the level with braces, crutches and a corset, but cannot go up or down stairs on his crutches without assistance.

CASE 4.—*Fracture of the spine.*—A girl, aged 19, referred by Drs. Scott, Sherwood and Brindley, of Temple, Texas, had been injured in an automobile accident in August, 1916, and immediately lost all power in both lower extremities, and sensation from the knees down, the loss extending up on the left thigh. She had a deformity in the dorsolumbar region, and the roentgen ray revealed a fracture of the twelfth dorsal vertebra, with some side displacement. Laminectomy was performed three days later, and a ridge of bone was found compressing the cord. The ridge was cut away, but there was no improvement immediately following the operation, and retention of urine persisted for over a year. At the end of a year she was still unable to control the bowels.

The patient was seen by me in July, 1918, and at this time she had a well marked kyphos at the seat of fracture, the functions of the bladder and rectum were nearly normal, sensation was normal to a point 2 inches below the knee on both sides, knee jerks were lost, and ankle clonus was absent. There was practically no motion in the lower extremities, but there was some slight power left in the hip muscles. The girl had never stood or walked since the accident.

She was equipped with braces and a corset, and in a month was walking without assistance. In January, 1919, she wrote: "I am walking with my crutches every day, and gaining strength all the time. With the crutches I am most confident."

CASE 5.—*Fracture of the spine.*—A girl, aged 11 years, was referred by Dr. C. S. Buchanan of Bennington, Vt., and admitted to the Children's Hospital in February, 1920. In June, 1919, she had fallen out of a tree and sustained a compression fracture of the eleventh dorsal vertebra, which was very evident in the roentgenogram taken at the time of her admission to the hospital. Sensation and motion were immediately lost below the level of the injury, and paralysis of the bladder and rectum was present. A laminectomy had been immediately performed, but it was followed by no improvement, and she had been helpless, so far as getting about was concerned. Power in the legs was entirely absent; there was a trace of power in the muscles of the hips, but not enough to move the limbs. Sensation was wholly absent below the level of the injury. At the time of her admission to the hospital, function of the bladder and rectum had returned, but there was a considerable kyphos in the lower dorsal region.

She was fitted with caliper braces and taught to use the crutches in the tripod fashion. In March, 1920, she was able to walk the length of the hospital corridors, and could get up and down from her wheel chair without assistance by taking hold of the bottom of the bed. She developed a pressure sore which lasted for a few days on one of the toes from too much walking, which is a warning of how careful one

must be in regard to pressure from brace or shoe in cases with total abolition of sensation.

COMMENT

These cases have been selected from a fairly large number of similar ones, as they were obviously severe and some of them of fairly long standing.

They show that persons with very low grades of power in the legs, hips, abdomen and back can be taught to walk, to get up and down from a chair, and many to go up and down stairs. The two latter achievements constitute the difference between independence and dependence in the life of the affected person.

CONCLUSION

It need only be repeated that any intelligent patient with flaccid paralysis below the waist, with one good arm and one arm good enough to hold a crutch, can be taught to walk by the tripod method, and to get up and down out of a chair unaided, provided contraction deformities are not present, or have been removed by operation.

234 Marlborough Street.

MECKEL'S DIVERTICULUM

REPORT OF CASE

DANIEL L. BORDEN, A.M., M.D.

Associate Professor of Surgery, George Washington University
WASHINGTON, D. C.

Owing to the rarity of its pathologic lesions, Meckel's diverticulum presents an interesting study. The case here reported, although terminating fatally,

Fig. 1.—Appearance of Meckel's diverticulum when abdomen was first opened. The diverticulum is protruding up through distended intestine.

offers an unusual feature which makes it worthy of consideration.

Meckel's diverticulum is an occasional sacculation, cecal appendage or tube of the ileum, produced when the intra-embryonic segment of the vitelline duct fails to close. This closure should occur normally about the fifth week of fetal life.

Historically this condition was first described by Rysch, an anatomist, but it was not until 1808 that

Meckel gave to the scientific world an accurate and minute account of this abnormality. He showed that the diverticulum existed either as a free blind pouch

appendix. Like the appendix, therefore, in the closed type of diverticulum it is subject to ulceration, catarrh, perforations and gangrenous inflammation, and often it is a haven for foreign bodies. Apple seeds, grape seeds, cherry stones, fish bones and, in one instance, a Murphy button have been reported found in its lumen.

Either the pouch or band form of diverticulum offers opportunity and possibility for bowel obstruction. In the band form the intestine becomes twisted about, or strangulated by the band in much the same manner that it does in some forms of post-operative adhesions. In the pouch form, there is possibility of the diverticulum's invaginating itself into the intestinal lumen, producing a certain degree of obstruction with ultimate intussusception. On the other hand, as in the case here reported, the free diverticulum may tie a knot about itself, including a loop of intestine.

Owing to its rarity and its similarity to both acute appendicitis and intestinal obstruction, the differential diagnosis of a pathologic condition of Meckel's diverticulum is not usually made until the abdomen is opened.

The treatment of uncomplicated diverticulum is similar to the surgery of the appendix. The diverticulum is resected and the stump inverted into the ileum.

or as a tube attached to the anterior abdominal parietes, generally at the umbilicus. This tube may be closed or open; and when open, it forms the so-called congenital fistula, discharging fecal material through the umbilicus. The blind pouch diverticulum varies in length from 2 to 25 cm. and is usually located on the free border of the intestine between 4 and 90 cm. from the ileocecal valve. Structurally, being a part of the alimentary unit, the diverticulum is composed of four coats similar to the intestine, namely, serous, subserous, muscular and mucous.

As Meckel's diverticulum is a developmental defect derived from an unobliterated vitelline duct, it presents some statistical facts of interest. The condition is seen in only 2 per cent. of human beings, and in this 2 per cent., few come to the attention of the surgeon, for, unless they are complicated by a pathologic condition or discovered by accident at abdominal section, their presence is never known. Balfour reports only fifteen cases of diverticulum out of 10,600 laparotomies performed at the Mayo Clinic during a period of three years. Pathologic complications of the diverticulum are more commonly seen during active middle life, and they occur in males more frequently than in females. Out of a collected series of 130 cases, Keen reports its occurrence in 100 males to thirty females.

Uncomplicated Meckel's diverticulum, unless it is a congenital fistula, produces no symptoms. As the diverticulum is an intimate part of the small intestine, it is subject to the various pathologic lesions seen in the ileum and the acute inflammations similar to those of its neighbor, the

Fig. 2.—Strangulated intestine and Meckel's diverticulum after resection.

Fig. 3.—Diagrammatic representation of successive steps in knot tied by diverticulum around loop of intestine.

In the event of a pathologic complication involving Meckel's diverticulum, the surgeon may be confronted by extremely serious conditions.

REPORT OF CASE

History.—F. J., aged 26, white, married, private, Company G, engineers, whose mother, father, five brothers and four sisters were living and well, had a negative history except for a severe burn on the left side of the face in childhood, had always been well, and denied any previous abdominal trouble. The present illness began suddenly at 10 p. m., April 4, 1918. The patient was walking home, after having taken a cup of coffee and a piece of toast, when he experienced a sudden cramplike pain in the lower right quadrant of the abdomen. The pain was so severe that he had to be taken to his station at the Washington Barracks, Washington, D. C. He vomited continually throughout the entire night, and suffered constant and severe abdominal pain. Next morning he was transferred by ambulance to the Walter Reed General Hospital, where he was seen at noon, fourteen hours after the onset of the attack.

Physical Examination.—The patient weighed 130 pounds. His facial expression was extremely anxious, pinched and exhausted. His general appearance was very bad and gave every evidence of a severe intra-abdominal complication. There was notable general rigidity of the abdominal wall,

Fig. 4.—Photograph of gangrenous mass, intestine and diverticulum.

with the rigidity somewhat accentuated over the lower right quadrant. Tenderness was also general, but more marked over McBurney's point. No abdominal mass was palpable. A tentative diagnosis of ruptured appendix was made and immediate operation urged.

Operation and Result.—Through a right rectus incision the abdomen was opened, when a large amount of bloody, foul, fecal smelling peritoneal fluid escaped. A dark gangrenous mass 4 inches long and 1 inch in diameter protruded through distended coils of intestine. Careful separation of the loops of intestine and a following of the mass to its base revealed that it led to a long coil of gangrenous intestine. When this green gangrenous mass of strangulated intestine was liberated there was a marked odor of colon. A diagnosis of Meckel's diverticulum with strangulation and bowel obstruction was evident.

The mesentery of the strangulated intestine was involved down to its postperitoneal attachment, making resection very difficult. The mass, however, was excised and an end to end suture anastomosis was done. To determine the size of the opening at the point of anastomosis, the bowel was inverted by the index finger at the point of union. The lumen seemed amply large. The abdomen was drained and closed in layers. The patient, although shocked, left the table in fair shape considering his previous condition.

April 6, twenty-four hours after operation, the patient's general condition was unquestionably better. On this day he passed a fair quantity of gas but no fecal matter. April 7, he continued to pass gas, but there was some distention. April 8, there was marked distention with signs of obstruction. He began vomiting, and operation seemed imperative. Under local anesthesia an enterostomy was performed, at which time 2 quarts of fecal matter were evacuated. His condition continued very grave, and on April 9 he was given 500 c.c. of blood. Although temporarily improved by this, he died at 9 p. m.

Necropsy.—The enterostomy opening was found 145 cm. from the cecum. Above the enterostomy the small intestine was distended with gas and fecal matter. The end-to-end anastomosis was found 40 cm. from the cecum. At the point of anastomosis there was an indurated mass obstructing the bowel. There was no evidence of leakage from the bowel into the peritoneal cavity.

COMMENT

The case presents an unusual pathologic lesion of Meckel's diverticulum. As is shown in the illustrations, the diverticulum had tied itself into a complete knot, around the base of, and strangulating a coil of intestine about 2 feet in length. In order to untie this knot the diverticulum had to be cut near its base and the path of the tie of the diverticulum retraced by means of a hemostat. Mr. W. H. French, the artist, was present at the operation, and very kindly made an accurate drawing illustrating the picture presented at operation as well as the manner in which the diverticulum was tied.

815 Connecticut Avenue.

THE CATALASE CONTENT OF THE
CEREBROSPINAL FLUID*

ABRAHAM LEVINSON, M.D.

AND

FRANK C. BECHT, M.D.

CHICAGO

The presence of catalases in the cerebrospinal fluid is still more or less of an open question. Barbieri¹ concluded that no catalases are to be found in the fluid—a conclusion to be expected from the method he employed, as all his results are from fluids subjected to prolonged centrifugalization followed by the withdrawal and testing of the supernatant fluid. It has already been shown,² that the blood serum contains no catalase when fully freed from corpuscles. Thus, a similar result is to be expected from the liquid portion of the cerebrospinal fluid.

METHOD AND RESULTS

In this work the apparatus described by one of us was employed.³ The peroxid used was the ordinary commercial 3 per cent. solution, acid in reaction and with acetanilid added as a preservative. The solution was neutralized immediately before the test by the addition of the required amount, 1.5 c.c. of half normal sodium hydroxid; one c.c. of fluid and 25 c.c. of hydro-

gen peroxid were used in each test. The bottles were shaken for ten minutes in each case. Because of the small amounts of oxygen released, no correction was made for temperature and pressure. Most of the tests were run in duplicate only, on account of the difficulty in securing enough fluid. It was impossible to make cell counts in all cases.

The results of our experiments are given in the accompanying tables.

Table 1 shows the findings in eight fluids secured from nonmeningitic cases. In no case was more than 5 c.c. of oxygen generated and, therefore, it is evident that in nonmeningitic cases, in which the number of cells is small, the catalytic power of the fluid is negligible.

Table 2 shows the findings in three cases of tuberculous meningitis and one case of anterior poliomyelitis. In two cases the amount of oxygen released was greater than in nonmeningitic cases, and in two cases quite comparable to the amounts released in the fluid in Table 1.

Table 3 shows the findings in ten observations on suppurative meningitis. In general, the results here are an increased amount of oxygen released from hydrogen peroxid by the action of the fluid. The increase is by no means parallel with the number of cells, but a fluid with a large number of cells is usually a fluid with a relatively high catalytic power. The

S. B.	Tuberculous meningitis	12/11	2½ days	3, 2	4 red cells no white cells	Tubercle bacilli in fluid

pellicle when added to a test markedly increased the amount of oxygen released. Fluid that gave a fairly high catalase reading directly after the fluid was removed from the body gave a lower reading if examined after the fluid had been standing. This shows that the catalase depends on the presence of leukocytes, and varies directly with the number of leukocytes present in the fluid. Since leukocytes degenerate on standing, the catalase reading becomes lower.

PRACTICAL VALUE OF THE CATALASE TEST

While the presence of catalase indicates the presence of many cells or of a coagulum in the fluid, we see no advantage in the catalase examination for practical purposes. The cell count done immediately after withdrawal of the fluid from the body will give more accurate information without necessitating the use of complicated apparatus.

TABLE 3.—FINDINGS IN SUPPURATIVE MENINGITIS

R. T.	Streptococcus meningitis	12/28	3½ hrs.	40 35, 65*	960	Streptococcus in great numbers; all tests positive

* The pellicle was included in these tests.

CONCLUSIONS

The catalytic power of the fluid is determined by the number of cells or coagulum present, thus, perfectly normal fluid free from cells and coagulum contains no catalase.

The catalase test as applied to cerebrospinal fluid is of no practical value.

THE ROENTGEN-RAY TREATMENT OF VERRUCA PLANTARIS

H. H. HAZEN, M.D.

Professor of Dermatology and Syphilology, Georgetown University School of Medicine, and Howard University School of Medicine.

AND

F. J. EICHENLAUB, M.D.

Instructor of Dermatology and Syphilology, Georgetown University School of Medicine.

WASHINGTON, D. C.

Search of the literature at our disposal has failed to reveal anything more than a casual reference to the roentgen-ray treatment of that most stubborn of all warts, the plantar variety. Sutton¹ speaks of it in connection with the use of carbon dioxid snow, and mentions it without giving technic or results. Shultz² speaks of it briefly in the same way. We can find no case reports showing actual results, the amount of treatment required, and the technic used. Our own

1. Sutton, R. L.: Am. J. M. Sc. **144**: 71 (July) 1912; An Extensive Case of Plantar Warts, J. A. M. A. **62**: 1320 (April 25) 1914.
2. Shultz: X-Ray Treatment of Skin Diseases, New York, Rebman Company, p. 145.

results have been so uniformly good that we present them with our technic.

We have records of sixteen private cases treated by the roentgen ray. All received the same general plan of treatment, individual cases requiring different amounts, as shown in the table. We are unable to assign any reason for this difference in response to treatment of lesions which are very similar in size, nature and duration. Some of those of longest duration responded most quickly to treatment, and neither size nor location appeared to play any part. Another peculiarity noted was that almost invariably the pain disappeared in from two to four days after the first treatment. Why this should be we cannot say, unless it is due to an action on the nerve terminals analogous to the action of the roentgen ray in pruritis. Since pressure, the cause of the pain, is in no way affected at this early stage, we can offer no other explanation.

Our technic is to give $1\frac{1}{3}$ Holzknecht skin units every three to four weeks. We estimate our dosage according to the method long advocated by MacKee,³ and recently described by him. In our work we use a

RECORDS OF SIXTEEN CASES TREATED BY
ROENTGEN RAY

Case No.	No. of Warts	No. of Treatments	Total H Skin Units	Result
1	1	3	4	Cured
2	1	2	$2\frac{2}{3}$	Cured
3	4	3	4	Cured
4	5	7	9	Not benefited*
5	1	3	4	Cured
6	1	2	$2\frac{2}{3}$	Cured
7	1	4	$5\frac{1}{3}$	Cured
8	1	3	4	Cured
9	6	3	4	Cured
10	1	1	$1\frac{1}{3}$	Cured
11	1	2	$2\frac{2}{3}$	Cured
12	1	2	4	Cured
13	4	4	$5\frac{1}{3}$	Cured
14	1	7	9	Cured†
15	20	3	4	Cured
16	1	2	$2\frac{2}{3}$	Cured

* In case 4 there were flat warts, a variety notorious for its resistance to roentgen-ray treatment, no matter where located.

† The patient in case 14 discontinued treatment before being cured and then had a recurrence which required a second course of treatments, thus accounting for the large number of units required.

$7\frac{1}{2}$ inch spark gap, 9 inches focal skin distance, 4 milliamperes, and one minute, ten seconds to obtain 1 H. When the lesion has disappeared we usually give an additional treatment to be sure of a complete cure. Hence many of those, who, as shown in the table, received two or more treatments, would have required one less had we given the minimum. It should be noted that we use no filter in this work, as we feel that on superficial lesions results are much better with the unfiltered ray.

The cure seems to be permanent. Some of our patients have been followed for five or six years, and have had no recurrence. On the basis of such results as these we have abandoned all other forms of treatment, using the roentgen ray alone, and quite confidently give a favorable prognosis. As the table shows, only one case, and that not the ordinary variety of plantar wart, has failed to respond true to form.

SIGNIFICANCE OF THE DIFFERENT TYPES OF PNEUMONIA FOLLOWING INFLUENZA

A THERAPEUTIC INDICATION

B. S. KLINE, M.D.

NEW YORK

In a study of the pulmonary lesions following influenza, the impression was gained that an associated pulmonary edema is a factor of great importance in determining the rapid extension of the inflammation

TABLE 1.—NUMBER OF LOBES INVOLVED

throughout the lung, and that in the absence of this edema, the lesion remains localized about the bronchial branches.

The observations recorded in this paper were made during the epidemic of influenza in the American Expeditionary Force hospital center at Bazoilles, Vosges, France, between Sept. 2 and Dec. 27, 1918.

About 200 patients died there with pneumonia following influenza, and of these, 154 came to necropsy. In all cases there was a tracheitis and bronchitis. The most striking lesion, however, was observed in the lungs. In the vast majority (86 per cent.), the consolidation was widespread, involving three or more lobes; in one half of the cases all five lobes were affected.

Table 1 shows the extent of the pulmonary involvement in the series.

The pulmonary consolidation in these cases varied in character; discrete lesions in some cases contrasted sharply with confluent consolidation in others. The discrete lesions were peribronchial and peribronchiolar; the confluent lesions were coalescing lobular in

TABLE 2.—INCIDENCE OF DISCRETE, CONFLUENT AND
COMBINED CONSOLIDATION

Type	Short, 1 Week or Less	Moderate, From 1 to 2 Weeks	Long, Over 2 Weeks	Total Cases
Peribronchial and Peribronchiolar	2	7	11	20
Coalescing Lobular	14	36	14	64
Combined Peribronchial, Peribronchiolar and coalescing lobular	10	33	27	70

type. A considerable number of the cases showed both discrete and confluent consolidation.

Table 2 shows the incidence of the three types.

In peribronchial and peribronchiolar pneumonia, the lung was quantitatively much less involved than in the other types, and this may explain the longer average duration of the disease and the smaller percentage of fatal cases of discrete pneumonia, as compared with the confluent pneumonias.

DESCRIPTION OF PULMONARY LESIONS

In the coalescing lobular pneumonia of short duration, the involved lobes are more voluminous than normally. They are heavy, soggy and solid. Excised

Differential Diagnosis.—In acute perforation the patient lies still, fearing to breathe; in gallstone colic he rolls about with pain.—Sir D'Arcy Power, *Surgical Aphorisms*. *Clin. J.* 49:28 (Feb.) 1920.

portions, when placed in water, settle down or submerge, but do not sink to the bottom of the container. On section of an involved lobe, a considerable portion, usually the posterior, or the entire lobe, is found consolidated; the surface is smooth, moist and dark red. Over the cut surface a considerable amount of bloody fluid exudes from the air spaces. The picture is that of congestion, edema, hemorrhage and consolidation of entire lobules or portions of these, with extensive coalescence of the inflammatory process. Scattered throughout the involved areas, there are seen lobules or groups of relatively little affected alveoli. The tissue is rubbery rather than friable, and is quite compressible.

In the coalescing lobular pneumonia of moderate duration, the involved lobes are more voluminous than normally; they are heavy and solid. Excised portions, when placed in water, submerge or sink to the bottom of the container. On section of an involved lobe, a considerable portion, usually the posterior, or the entire lobe is found consolidated; the surface is somewhat moist, finely granular and grayish red or gray. The coalescence of the inflammatory process is more striking than in the lesions of shorter duration, and suggests lobar consolidation. It differs from the hepatization in lobar pneumonia in that the cut surface of the involved lobe is less coarsely granular, the tissue much less friable and more compressible.

In the cases of long duration, the lesions vary. In some, the general features are similar to those described in the foregoing. In these old cases, however, the cut surface is coarsely granular and the tissue quite friable.

In others, the surface is pasty and the tissue is easily compressed, causing an exudation of moist, viscid fluid. There are also cases in which resolution is further advanced with scattered areas of pasty consolidation only about the bronchial branches. In the cases of longest duration, small or large portions are firm, grayish, somewhat translucent, and traversed by gray flecks and strands.

In the peribronchial and peribronchiolar pneumonia, the involved lobes are more voluminous than normally. They are cushiony and solid, or cushiony, soggy and solid. On section a considerable amount of relatively uninvolved tissue is seen; the consolidation is localized about the bronchial branches, and extends from a few millimeters to several centimeters from the lumen. In this type, the oldest lesions are frequently seen near the hilum of the lobe.

The discrete consolidation varies in appearance, depending on the duration, and shows changes comparable to those described in the confluent pneumonia. It differs, however, in that in cases of short and moderate duration, the consolidated tissue is much less moist than that of the type described above.

In the combined peribronchial, peribronchiolar and coalescing lobular pneumonia, the involved lobes show a combination of the changes described in the discrete and confluent pneumonias.

In over one half of the cases there was an associated pleurisy, usually slight. Not infrequently, a terminal edema was noted in cases of each type.

These cases were studied bacteriologically by Dr. R. C. Curtis. Pneumococci, *Bacillus influenzae*, and *Micrococcus catarrhalis* were recovered in about the same percentage in the three types. In all cases the

myocardium showed parenchymatous changes, and in the majority, dilatation of the right heart was observed postmortem.

COMMENT

From the observations noted in the foregoing, it would seem that in some cases following a tracheitis and bronchitis, pulmonary congestion and edema occur, and the inflammatory process extends from the bronchi throughout the edematous lung, producing the widespread coalescing lobular consolidation.

In other cases following the tracheitis and bronchitis, there is little if any pulmonary edema, and the inflammatory process extends only a small distance beyond the bronchial branches, producing a discrete peribronchial and peribronchiolar consolidation.

There is a third type of cases in which the tracheitis and bronchitis is followed by an extension of the inflammatory process about the bronchial branches; and following this discrete pneumonia, there is extensive pulmonary congestion and edema with extension of the process from about the bronchial branches throughout the lobe, producing a coalescing lobular consolidation.

A detailed histologic report of the lesions will be given later, but at this time it may be stated that histologically the sections corroborate the impression of extension of the inflammation through edematous lung in cases of coalescing lobular consolidation and of absence of associated edema in peribronchial pneumonia.

A factor of great importance in determining the rapid extension of the inflammation throughout the lung, if the foregoing hypothesis is correct, is the associated pulmonary edema. In the absence of pulmonary edema the lesion remains discrete and the disease is less severe.

Digitalis and venesection are each reported¹ to have a beneficial action in pneumonia following influenza. It may be that these measures are instrumental in preventing pulmonary edema, thus limiting the extension of the inflammation.

CONCLUSION

There is evidence for the belief that in pneumonia following influenza, an associated pulmonary edema is a factor of great importance in determining the rapid extension of the inflammation throughout the lung, and that in the absence of this edema, the lesion remains localized about the bronchial branches.

G.: The Influenza Pneumonia Epidemic at Camp Dodge, Am. J. M. Sc. 158:212 (Aug.) 1919. Ravaut, P.: Treatment of Influenza, Paris méd. 8:390 (Nov. 16) 1918, p. 390.

Tuberculosis and Occupation.—The latest occupational mortality statistics for the United States for 1909 show that the mortality from tuberculosis in agricultural pursuits was 8.7 per cent.; among bookkeepers and accountants, 22.5 per cent.; and in servants and waiters, 27.4 per cent. If we stop right here the evidence would be overwhelming in favor of outdoor employment. But when we find that the tuberculosis mortality in government officials and bankers is less than 8.7 per cent., and that for draymen, hackmen and teamsters it is 23.4 per cent., it becomes apparent that in estimating the hazards of indoor occupations, other factors, such as physique, habits, exposure to dust, social conditions and standards of living must be considered.—G. M. Kober, *Pub. Health Rep.*, March 26, 1920.

VENEREAL PROPHYLAXIS

P. M. ASHBURN, M.D.

Colonel, Medical Corps, U. S. Army

WASHINGTON, D. C.

In a recent article¹ I expressed the opinion that venereal prophylaxis or "early treatment" after an impure sexual connection reduces the liability to venereal infection to one third of what it would be without it, and that in France, where practically all exposures on the part of our troops could fairly be considered impure and at least potentially infectious, there resulted one infection to thirty exposures without the use of prophylaxis, and one infection to ninety exposures followed by its use. Many officers who had thought prophylaxis more efficient than these figures indicate raised the objection that men who acquired infection after the use of prophylaxis did so as a result of failure to use it promptly or properly.

Concerning the charge that it was not used properly, I suspect that such was the case in many instances; but vigorous and continued efforts were and are made to see that it should be so used. Perfection is not likely to be obtained, but a reasonably good technic is applied in most instances.

TABLE 1.—TIME ELAPSING BETWEEN INFECTING INTERCOURSE AND USE OF PROPHYLAXIS

Time Within Which Prophylaxis Was Used	Cases	
	No.	Per Cent.
15 minutes	132	5.6
30 minutes	438	18.5
45 minutes	510	21.6
1 hour	1,015	43
2 hours	1,629	69
3 hours	1,884	79.8
4 hours	1,998	84.6
After 4 and within 12.....	196	8.3
Period not stated.....	165	6.9

Concerning the charge that prophylaxis was not or is not promptly used by persons acquiring infection, I now have some testimony. Since early in September, 1919, a questionnaire accompanied by the following statement from the Surgeon-General of the Army has been submitted to each patient in whom a new case of venereal disease was detected:

The soldier will be informed that this information is desired for use in the control of venereal disease, that it will be held confidentially and not used to his detriment, that he is under no compulsion to furnish it but that information will be appreciated. He will be asked to tell the truth or to refuse to answer, but to avoid making misleading statements. A report of this sort will be sent in on each new case of venereal disease detected, but if the soldier refuses to furnish any of the information asked for, that fact will be stated.

By Feb. 26, 1920, 5,000 case reports had been received and compiled; 4,755 men answered the question as to whether or not their infections followed the use of prophylaxis, of which number 2,359 men said that theirs did. The answers of these 2,359 men as to the time elapsing between the infecting intercourse and the use of prophylaxis are given in Table 1.

It is apparent that efforts at disinfection of a penis, as of hands or throat, cannot always be successful, even though the effort be made very soon after the exposure to infection. There is much the same reason, however, for making the attempt at disinfection that

there is for a surgeon's attempting to disinfect the hands which he has contaminated or injured while operating on a syphilitic or suppurative lesion, and more reason, so far as the available evidence indicates, than for attempting to disinfect a throat exposed to infection from any one of the respiratory diseases.

Among these 5,000 infected men the average number of sexual contacts followed by prophylaxis was, for the preceding year, 15.3 for each infection follow-

TABLE 2.—COMPARISON OF EFFECT OF PROPHYLAXIS ON THREE VENEREAL DISEASES

	Gonorrhea Per Cent.	Chancroid Per Cent.	Syphilis Per Cent.
Without prophylaxis	67.2	15.6	17.2
With prophylaxis	64.5	18.9	16.6

ing its use, while the average number of contacts without prophylaxis was, during the same period, 11.6 for each infection following its neglect. In order to determine, if possible, whether the use of prophylaxis prevents one type of venereal disease more than it does others, a comparison was made of the relative proportions of the three diseases in the first 2,000 cases in which infection followed the use, and in the first 2,000 in which it followed neglect of prophylaxis. The results are given in Table 2.

This comparison shows differences, but they are not so great as might be expected. The suggested causes of them are:

(a) Chance: They may be due to the run of the (report) cards; i. e., it may be that an undue proportion of the cards showing the use of prophylaxis relate to men who contracted the diseases in the Philippines, Europe or some other foreign part where chancroid is more common than in the United States.

(b) Greater carelessness in the use of one feature of the prophylaxis than of others; e. g., it may be that thorough inunction is relatively neglected.

(c) Contamination due to rubbing; i. e., friction of inunction may cause cracks and abrasions and so permit the entrance of pyogenic organisms, which cause ulcers diagnosed as chancroids.

TABLE 3.—PERCENTAGE OF VENEREAL DISEASES AMONG UNITED STATES TROOPS FROM 1903 TO 1915

Year	Diseases		
	Gonorrhea Per Cent.	Chancroid Per Cent.	Syphilis Per Cent.
1903.....	61	20	17
1904.....	65	17	17
1905.....	66	17	16
1906.....	66	16	17
1907.....	64	20	15
1908.....	70	16	13
1909.....	69	14	15
1910.....	65	16	17
1911.....	57	15	27
1912.....	60	17	22
1913.....	57	17	24
1914.....	57	22	20
1915.....	60	18	20

(d) Effect of urinating. The urination always practiced with prophylaxis may be an important factor in the prevention of gonorrhea.

(e) Normal variations. The differences in percentages may be merely such as are within the normal variations that occur in large groups of cases, and without significance. Table 3 shows the percentages of these three diseases in the totals of venereal disease reported among troops serving in the United States

1. Ashburn, P. M.: Factors Making for a Low Venereal Record in the American Expeditionary Forces, J. A. M. A. 73:1823 (Dec. 13) 1919.

for the years 1903 to 1915. The increase in syphilis after 1910 is probably attributable principally to the use of the Wassermann test.

OCCURRENCE OF BILATERAL SYMPATHETIC OPHTHALMOPLEGIA

ITS SIGNIFICANCE IN LETHARGIC ENCEPHALITIS

WILLIAMS B. CADWALADER, M.D.

Instructor in Neurology and Neuropathology, University of Pennsylvania School of Medicine; Neurologist, Presbyterian Hospital

PHILADELPHIA

I wish to call attention to the diagnostic importance of the occurrence of bilateral sympathetic ophthalmoplegia in cases of lethargic encephalitis. So far as I know this has not been previously recorded, and it is of great significance in the diagnosis of this disease.

It is well established that the pons and the medulla oblongata are traversed by a tract containing oculopupillary fibers. A lesion of this tract causes contraction of the pupil and narrowing of the palpebral fissure and slight retraction of the eyeball of the same side.

The tract passes through the dorsomedial region of the pons and medulla oblongata. Focal disease of the pons and medulla may therefore produce symptoms of "sympathetic ophthalmoplegia." This sign, however, so far as I know, has not previously been observed on the two sides at the same time. Recently I have had two cases of lethargic encephalitis in which both pupils were contracted and both palpebral fissures were narrowed, that is, the signs of bilateral "sympathetic ophthalmoplegia." In one of these the clinical diagnosis was confirmed by postmortem examination.

Bilateral involvement of the sympathetic fibers of the eyes can be caused only by a diffuse or inflammatory lesion of the brain stem, so that when it is associated with the characteristic mental confusion of lethargic encephalitis it should be regarded as a diagnostic sign of that disease.

However, because of the bilaterality of the narrowing of the palpebral fissures and contraction of the pupils, it is not likely to attract attention and is overlooked; but when it occurs only on one side at the time, the contrast quickly directs attention to it.

Bilateral sympathetic ophthalmoplegia is not known to occur in other diseases.

1501 Spruce Street.

Industrial Health Hazards.—An industrial health hazard should be interpreted to mean any working condition which is responsible for or contributes to physical injury or illness, including the presence of poisonous fumes, vapors, gases, liquids and most factory dusts; excessive heat, cold and humidity; the handling of materials known to retain or suspected of retaining harmful bacteria; the frequent lifting of heavy weights, long hours of labor, muscular strain, and like conditions which predispose workers to disease. It is alleged, for instance, that there are over 600 branches of industry where poisonous fumes, gases, or liquids are present, and more than sixty-five industries in which dust is a menace to health. There are an unknown number of processes where fatigue is the result of muscular strain, and where organic weakness of the workers, often unknown to them, increases susceptibility to occupational disease. In view of this situation is it not advisable to know the effect on health of varying plant and municipal conditions? When the cost of information is so relatively slight, what objection is there to provision for the veritable barometer of health which morbidity statistics create?—*Pub. Health Rep.*, April 9, 1920.

Clinical Notes, Suggestions, and New Instruments

A DEVICE FOR THE INTERMITTENT FLUSHING OF WOUNDS

EDGAR G. BALLENGER, M.D., AND OMAR F. ELDER, M.D.,
ATLANTA, GA.

By means of the device shown in the accompanying illustration, wounds may be flushed intermittently with medicating solutions, such as surgical solution of chlorinated soda (Dakin's solution), every half hour, two hours or otherwise

as desired. It has merely to be connected to an irrigating container and the screw compressor on the tube leading from it so adjusted that a given number of drops flow per minute. When the fluid collects to the level of the tube at C, siphonage is established and the solution flows through the exit tube into the wound.

The amount may be varied by raising or lowering the tube at C, while the frequency of the flushing is regulated by the rate of the drops per minute. In this manner wounds may be flushed with solutions as desired without the necessity of a nurse or an attendant, the only thing necessary being to keep the solution in the irrigating container, which may be of sufficient size to last for twenty-four hours.

The hole in the rubber stopper B permits siphonage, when established, to empty the solution collected in the apparatus.

The force with which the solution comes into the wound can be varied as desired by the height to which the device is carried above the wound.

Multiple connections may be made as desired. When a continuous drip is needed, it is only necessary to remove the tube from C and allow it to hang.

If we had had such a device in France, the employment of Dakin's solution would have been much less troublesome than it was.

It is as simple to use as the rectal drip, being altogether automatic; it greatly lessens the work of the nurses, and at the same time gives treatment exactly on time.

Device for intermittent flushing of wounds.

LETHARGIC ENCEPHALITIS AS A COMPLICATION OF PREGNANCY AND LABOR

A. Y. P. GARNETT, M.D., WASHINGTON, D. C.

A woman, aged 26, secundipara, had a fairly typical attack of lethargic encephalitis beginning about February 6, when she was eight months pregnant. Her family history and previous personal history were negative; the menstrual history was negative, and her previous labor, eighteen months before, had been normal. Until February 6 she had been normal, and there had been no complications of her pregnancy. At this time she became nervous, complained of tingling in the arms and legs and extreme weakness. The temperature was 102.5. Later she became semidelirious and restless. At this time she was seen by Dr. Loren Johnson, Dr. Moore and Dr. Hough in consultation, and a diagnosis of lethargic encephalitis was made. The symptoms were typical. There was diplopia, ptosis of the lids, nystagmus and marked mental and physical exhaustion. The patient's mind wandered, her

answers to questions became vague and rambling, her eyes closed and she apparently lapsed into sleep after very slight mental or physical effort. The pupillary reflexes were sluggish, the tendon reflexes hyperactive, and the superficial abdominal reflexes absent. There was no Babinski reflex or Kernig sign, and no nuchal rigidity. The heart and lungs were negative; the pulse, 100, regular in force and frequency; the systolic blood pressure 110 and the diastolic, 70. The urine was negative. The blood showed a normal white blood cell count and differential, and a moderate secondary anemia; a blood culture was negative. The blood Wassermann test was negative, and an examination of the spinal fluid by Dr. Hough revealed a clear fluid under moderately increased pressure, with protein content increased $++$, 18 cells per cubic millimeter, Wassermann test negative, and colloidal gold test negative.

The patient had been removed to Garfield Hospital, as the home surroundings were not suitable for treating a case of this sort. The pregnancy at this time was normal in every way; the head was not engaged and was in the left occipito-anterior position; the fetal heart was 140 and regular. The temperature was irregular, at first occasionally rising to 101 or 102.5, the highest it reached at any time, and later becoming normal or subnormal. The pulse was rapid, from 100 to 120. The blood pressure continued somewhat below normal. For two weeks previous to labor the patient complained of great pain in the legs, which I thought was aggravated possibly by pressure of the head in the pelvis. I therefore raised the buttocks on a pillow, and elevated the head away from the pelvis.

Her mental and general physical condition gradually and slowly improved, but was far from normal when she went into labor, February 29. When labor began the head was unengaged in the right occipitoposterior position with the occiput inclining to the right iliac fossa. The pains developed rapidly, were strong and when she was nearly fully dilated the head was easily brought over into the pelvis, rotated to the anterior position, and the membranes ruptured. The patient went through a normal delivery in two hours, and had no undue bleeding afterward, and apparently no shock. Her pulse was 90 at the beginning of labor, and 106 at the end. There was no complaint of the labor pains. She apparently did not suffer at all, and said that though she felt them, the pains caused her little or comparatively little suffering. She had no anesthetic from beginning to end. She was returned to the ward in good obstetric condition. Though the night nurse was ordered to catheterize the patient, this was overlooked, and she passed no urine until the following morning. When I saw her at this time the uterus was fairly well contracted, the entire lower abdomen distended though not painful, the bladder on a level with the fundus of the uterus. Catheterization produced 72 ounces of urine.

The baby was a normal infant weighing $6\frac{1}{2}$ pounds. The puerperium has been perfectly normal with no fever and no pain and though the milk was very scanty she has endeavored to nurse her baby. She has had no inclination to void, and there appears to be a partial paralysis of the bladder. Though allowed on the commode for half an hour at a time, she cannot void until the bladder contains at least 40 ounces of urine. Her mental condition has continued to improve and has cleared up, until now, with the exception of an occasional hallucination and some pain in the legs, she has perfectly recovered. There has been no treatment except for the anemia. For this she was given ten injections of sodium cacodylate, and at present her hemoglobin is 80 per cent. and the red blood count, 4,100,000, which is an improvement. The spinal fluid was examined again, March 12, by Dr. Hough, and showed a clear fluid, under normal pressure, with protein content $+$, and 9 cells per cubic millimeter, which is not quite normal but indicates improvement.

The particularly interesting part of this case to me from an obstetric point of view is the apparently painless labor and the partial paralysis of the bladder, indicating that there may have been some destruction of the posterior nerve roots simulating tabes dorsalis.

1824 Massachusetts Avenue.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

PITUITOL OBSTETRICAL.—Pituitary Extract Obstetrical-Hollister-Wilson. An extract of the posterior lobe of the pituitary body of cattle, approximately three times the strength of Solution of Hypophysis, U. S. P., preserved by the addition of chlorbutanol, each Cc. containing 0.005 Gm. It is standardized according to the method of G. B. Roth (Bulletin 100, U. S. Hygienic Laboratory).

Actions and Uses.—See general article Pituitary Gland, New and Nonofficial Remedies, 1920, p. 205.

Dosage.—0.3 to 1 Cc. (5 to 15 minims) hypodermatically or intramuscularly.

Manufactured by the Hollister-Wilson Laboratories, Chicago. No U. S. patent or trademark.

Ampoules Pituitol Obstetrical 0.5 Cc.—Each ampoule contains pituitol obstetrical 0.5 Cc.

Ampoules Pituitol Obstetrical 1 Cc.—Each ampoule contains pituitol obstetrical 1 Cc.

PITUITOL SURGICAL.—Pituitary Extract Surgical-Hollister-Wilson. An extract of the posterior lobe of the pituitary body of cattle approximately six times the strength of Solution of Hypophysis, U. S. P., preserved by the addition of chlorbutanol, each Cc. containing 0.005 Gm. It is standardized according to the method of G. B. Roth (Bulletin 100, U. S. Hygienic Laboratory).

Actions and Uses.—See general article Pituitary Gland, New and Nonofficial Remedies, 1920, p. 205.

Dosage.—0.3 to 1 Cc. (5 to 15 minims) hypodermatically or intramuscularly.

Manufactured by the Hollister-Wilson Laboratories, Chicago. No U. S. patent or trademark.

Ampoules Pituitol Surgical 1 Cc.—Each ampoule contains pituitol surgical 1 Cc.

RADIUM BROMIDE (See New and Nonofficial Remedies, 1920, p. 238).

Radium Bromide, Radio Chemical Corp.—Supplied in the form of a mixture of radium bromide and barium bromide. All deliveries are made subject to the tests of the U. S. Bureau of Standards.

Manufactured by the Radio Chemical Corp., New York.

RADIUM CARBONATE (See New and Nonofficial Remedies, 1920, p. 239).

Radium Carbonate, Radio Chemical Corp.—Supplied in the form of a mixture of radium carbonate and barium carbonate. All deliveries are made subject to the tests of the U. S. Bureau of Standards.

Manufactured by the Radio Chemical Corp., New York.

RADIUM CHLORIDE (See New and Nonofficial Remedies, 1920, p. 240).

Radium Chloride, Radio Chemical Corp.—Supplied in the form of a mixture of radium chloride and barium chloride. All deliveries are made subject to the tests of the U. S. Bureau of Standards.

Manufactured by the Radio Chemical Corp., New York.

RADIUM SULPHATE (See New and Nonofficial Remedies, 1920, p. 241).

Radium Sulphate, Radio Chemical Corp.—Supplied in the form of a mixture of radium sulphate and barium sulphate. All deliveries are made subject to the tests of the U. S. Bureau of Standards.

Manufactured by the Radio Chemical Corp., New York.

PROCEEDINGS OF THE NEW ORLEANS SESSION

MINUTES OF THE SEVENTY-FIRST ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT NEW ORLEANS, APRIL 26-30, 1920

(Continued from page 1257)

HOUSE OF DELEGATES

Third Meeting—Tuesday Morning, April 27

The House of Delegates met at 9:30 a. m., and was called to order by the Speaker.

The minutes of the previous meeting were read, corrected, and approved.

Dr. H. B. Gibby, Pennsylvania, Chairman, presented a supplementary report for the Committee on Credentials, stating that 110 delegates had registered, were entitled to and had been seated in the House of Delegates.

It was moved and seconded that the report be accepted. Carried.

Report of Reference Committee on Sections and Section Work

Dr. Hugh T. Patrick, Illinois, Chairman, presented the report of the Committee on Section Work, as follows:

To the House of Delegates:

The first part of the report of the Council on Scientific Assembly relates to an International Congress of Obstetricians and Gynecologists. The Council took no action on this.

Concerning the present plan of half day sessions of the sections, your committee conferred with the Secretary of the Association. As a result, he volunteered to request the officers of the sections to get, so far as possible, the sense of the members on this plan, this information to be for the future use of the Council on Scientific Assembly.

The remainder of the report of the Council on Scientific Assembly relates to matters involving changes in the By-Laws, and consequently your committee recommends that this part of the report be referred to the Reference Committee on Constitution and By-Laws.

Respectfully submitted, HUGH T. PATRICK, Chairman,

LEE MASTEN FRANCIS, S. R. ROBERTS,
FRANK E. McCULLOUGH, SOUTHGATE LEIGH.

It was moved that the report be adopted.
Seconded and carried.

Report of Reference Committee on Medical Education

Dr. J. N. Hall, Colorado, Chairman, presented the following report of the Reference Committee on Medical Education:

Your committee has considered the report of the Council on Medical Education, and wishes to commend the careful and thorough labors which have characterized the efforts of this Council these many years and from which the known improvement in medical education has resulted.

Your committee wishes particularly to endorse the intention of the Council to reclassify the medical schools on the basis of the present survey as detailed in the report, and herewith endorses the changes in classification which were reported. Concerning the routine work of the Council in relation to hospitals, your committee wishes to endorse the continuation of the various activities outlined in the report, and commends particularly the expressed intention of friendly cooperation with other agencies interested in hospital development.

Your committee endorses the efforts of the Council to secure a reorganization of academic education, allowing medical graduation at a less advanced age and to obtain extension of the facilities for graduate medical instruction.

Your committee is of the opinion that the much discussed plan of full-time clinical teachers is still in an experimental stage, and that no final judgment should be expressed at this time.

Relative to the "reorganization of medical education, wrong tendencies in clinical teaching and other tendencies in medi-

cal schools," your committee cannot endorse many of the statements made concerning preclinical instruction by non-medical men. While these unsatisfactory tendencies doubtless exist in many instances, they are generally due to economic conditions. It is at present impossible to obtain the required number of such teachers having complete medical training.

Your committee believes that this problem deserves further study, and also that each college should consider the need of a well balanced faculty to avoid such difficulty.

In general, however, your committee recommends the adoption of the report and urges the House of Delegates to lend every financial and moral support to the Council in the furtherance of its work.

Respectfully submitted,

L. HEKTOEN,

FREDERIC E. SONDERN,

J. N. HALL, Chairman,

W. H. SEEMAN.

Dr. M. L. Harris, Illinois, moved that the report be adopted.

Seconded and carried.

Report of the Reference Committee on Legislation and Public Relations

Dr. J. H. J. Upham, Ohio, Chairman, presented the report of the Reference Committee on Legislation and Public Relations, as follows:

The Reference Committee on Legislation and Public Relations had referred to it the reports of the Council on Health and Public Instruction and of the Special Committee on the Narcotic Drug Situation.

REPORT OF THE COUNCIL

Your committee has carefully considered the report of the Council, and is impressed by the broad scope of the field of operations covered by the Council and its committees and the progressive spirit shown in dealing with many problems of vital importance to the medical profession.

In accordance with the request of the Council, the committee has considered both the reports for 1919 and for 1920, and makes the following recommendations:

1. That the House of Delegates endorse and approve of Senate Concurrent Resolution No. 14, which has passed the U. S. Senate and is now pending in the House, providing for a joint congressional committee to make a survey and report on the federal public health activities, and that it urge its passage by the House. The creation of a congressional committee and the inauguration of a survey of federal public health work will furnish the fundamental information needed and will mark a long step forward in the securing of such a national health organization as our country requires.

2. That the medicolegal work of the Council, which has previously been endorsed by the House of Delegates, be approved and that the Council be directed to complete this work.

3. That the work of the Council in securing the passage of the model bill for the registration of births and deaths be approved, and that the state medical associations in Arizona, Nevada, South Dakota, Iowa and West Virginia, the only states now without adequate laws on this subject, be urged to take the lead in educating public opinion in these states and in securing the passage of the model bill at the next session of their legislatures, in order that the registration area may be completed and that birth and death registration, the basis of all modern health work, may be uniform throughout the entire country.

4. That the work of the Committee on Protection of Scientific Research be approved, and that the Council be directed to reprint the hearings before the Senate committee on the antivivisection bill as one of its educational pamphlets.

5. That the work of the Committee on Health Problems in Education be endorsed, and that the Secretary of the Coun-

cil be instructed to ask the secretary of each state association to have a committee appointed to attend the next meeting of the State Teachers' Association and to ask for the appointment of a committee from the State Teachers' Association to cooperate with the medical profession in promoting better health conditions in our public schools.

6. That the House of Delegates record its disapproval of the inequitable increase of the registration fee for physicians under the Harrison law and demand the reduction of this fee to a nominal amount so long as this law remains in force.

7. That the House of Delegates, while recognizing the fact that much good has been accomplished by the Harrison law, is of the opinion that the narcotic drug problem cannot be solved through any restrictive licensing system which permits of the importation of unlimited amounts of opium and cocaine, and that the only effective solution is for the federal government to take complete control of the importation of habit-forming drugs, the restriction of such importations to the amount required for legitimate purposes, and the distribution through the Public Health Service of such drugs to properly qualified and responsible persons.

8. That the Council on Health and Public Instruction be directed to inaugurate an investigation and submit a report on (1) the amount of narcotic drugs required each year for legitimate purposes; (2) the amount of narcotic drugs now actually imported, and (3) methods by which these drugs may be restricted to legitimate uses.

REPORT OF THE COMMITTEE ON THE NARCOTIC DRUG SITUATION¹

Your committee endorses the report of this committee, and desires to record its appreciation of the earnest and conscientious effort made to study this question and to present a synopsis of it to the House of Delegates. We recommend that the Council on Health and Public Instruction be directed to publish the report of the committee as one of its education pamphlets for distribution to those interested in the question.

We also recommend that the recommendations of the committee be adopted as follows:

1. That the ambulatory treatment of drug addiction, as far as it relates to prescribing and dispensing of narcotic drugs to addicts for self-administration at their convenience, be emphatically condemned.

2. That heroin be eliminated from all medicinal preparations, and that it should not be administered, prescribed or dispensed; and that the importation, manufacture and sale of heroin should be prohibited in the United States.

3. That the bill introduced by Senator France, No. 2785, and Representative Rainey, No. 11778, to provide aid from the United States from the several states in prevention and control of drug addiction and the care and treatment of drug addicts, be approved, and that Senator France and Representative Rainey be so notified.

4. In view of the statement in a government report that about 90 per cent. of the amount of narcotic drugs entered for consumption is used for other than medical purposes, the Treasury Department is respectfully urged to study and report on the narcotic drug situation, including the question of government control of these drugs.

5. That the Bureau of Public Health Service of the Treasury Department be respectfully requested to continue the compilation of state laws and regulations relating to habit-forming drugs, and bring them up to date.

Finally, your committee recommends that the report of the Council as a whole be adopted, and urges the Association to lend every encouragement and assistance to the Council in the continuation of its work.

Respectfully submitted,

S. E. LAMBERT,
LEROY CRUMMER,

J. H. J. UPHAM, Chairman,
FRANKLIN E. MURPHY,
J. E. LANE.

It was moved that the report be adopted.
Seconded and carried.

Report of the Reference Committee on Amendments to the Constitution and By-Laws

Dr. Rock Sleyster, Wisconsin, Chairman, presented the report of the Reference Committee on Amendments to the Constitution and By-Laws, as follows:

Your Committee on Amendments to the Constitution and By-Laws has carefully studied the suggested changes to the

Constitution and By-Laws as contained in the report of the Judicial Council and recommended for adoption by that body. Your committee has met with members of the Council and has received from them the final draft containing certain changes made after the printing of the handbook and not contained therein. Reasons for changes and the rewording of certain sections have been given and explained. The Chairman of the Council will be glad to explain further to the House the reasons for suggested changes if it is your desire as the sections are read.

Your committee finds no radical changes have been made. The Constitution and By-Laws have been brought up to date in keeping with the character of work done and the manner of doing it, the wording has been abbreviated and simplified, and the English improved. The Association is indebted to the Council for a much improved draft of a Constitution and By-Laws. The changes made by the Council since the printing of the handbook, together with some changes suggested by your committee, will be called to your attention in the reading. As submitted in this reading, it is approved by your committee and recommended for adoption.

Respectfully submitted,

W. B. RUSS,

EDWARD B. HECKEL,

ROCK SLEYSER, Chairman,

E. A. HINES,

A. E. BULSON, JR.

[NOTE.—The revised By-Laws are being printed, and will be ready for distribution in a few days. Copies will be sent on application.—Ed.]

On several motions, duly seconded and carried, each section was adopted, and on a separate motion, duly seconded and carried, the Constitution and By-Laws were adopted as a whole.

Dr. Horace M. Brown, Wisconsin, moved that the Secretary be authorized to make such editorial changes as to punctuation, paragraphing, etc., as may be necessary for the perfection of the record, but only such as shall in no wise modify the meaning of the portions so edited.

Seconded and carried.

Report of the Reference Committee on Miscellaneous Business

Dr. F. C. Warnshuis, Michigan, Chairman, presented the report of the Reference Committee on Miscellaneous Business, as follows:

Your committee had referred to it the communication of the Baltimore City Medical Society, requesting that this House of Delegates give serious consideration to the establishment of a medical newspaper devoted to health news and kindred subjects for the education and information of the lay public.

Your committee did not receive a copy of the article referred to in the communication.

Your committee readily perceives the benefits that might be derived from such a publication. However, so many factors exist that at this time we deem it inadvisable to enter on such an undertaking. The committee, therefore, recommends that this House of Delegates postpone for the present further consideration of this project.

Respectfully submitted,

CHARLES J. WHALEN,
N. B. VAN ETEN,

F. C. WARNSHUIS, Chairman,

GEORGE E. READING,
H. W. BELL.

It was moved that the report be adopted.

Seconded and carried.

The Secretary read a communication from Surg.-Gen. H. S. Cumming, United States Public Health Service, asking the House of Delegates to arrange for a representative of the American Medical Association to serve on a committee, acting under the Treasury Department, to study the distribution and use of habit-forming drugs.

The Speaker said that if there were no objections, this matter would be referred to the Council on Health and Public Instruction for action.

No objection being raised, it was so referred.

1. This report appears as an Addendum. See page 1324.

Resolution on Remuneration of Medical Officers in United States Civil Service

Dr. W. G. Morgan, District of Columbia, presented the following preambles and resolution, which were referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, The Congressional Joint Commission on reclassification of salaries has made certain recommendations concerning salaries of medical officers in the United States Civil Service, and such recommendations have been referred to the Committee on Reform in Civil Service, of the House of Representatives; and

WHEREAS, These recommendations are inimical to the interests of the medical profession, by subordinating the remuneration of medical officers to that of many others requiring less preparatory study: therefore, be it

Resolved, That the matter be referred to the House of Delegates for its consideration.

On motion, which was duly seconded and carried, the House of Delegates took a recess until 2 p. m.

Fourth Meeting—Tuesday Afternoon, April 27

The House of Delegates reconvened at 2 p. m. and was called to order by the Speaker.

Dr. H. B. Gibby, Pennsylvania, Chairman, presented a supplementary report for the Committee on Credentials, stating that 121 delegates had registered, were entitled to and had been seated in the House of Delegates.

It was moved and seconded that the report be accepted. Carried.

The report of the Reference Committee on Reports of Officers was called for.

Dr. Thomas S. Cullen, Maryland, Chairman, asked for further time, which was granted.

Dr. M. L. Harris, Illinois, Chairman of the Judicial Council, stated that under the By-Laws the Judicial Council made its own rules governing its work. There was an old standing rule which had been in operation for a number of years, but as these rules were not now in operation, since the Judicial Council had power to make its own rules, he moved that these old standing rules be rescinded.

Seconded and carried.

The Secretary read a communication, addressed to the President-Elect of the American Medical Association, extending an invitation to the members to visit the Cotton Exchange during their stay in New Orleans.

It was moved that the invitation be accepted.

Seconded and carried.

Report of Reference Committee on Hygiene and Public Health

Dr. J. W. Schereschewsky, U. S. P. H. S., Chairman, presented the report of the Reference Committee on Hygiene and Public Health, as follows:

Your committee has carefully considered the resolutions on compulsory sickness insurance, and reports it with amendments as follows:

Resolved, That the American Medical Association declares its opposition to the institution of any plan embodying the system of compulsory contributory insurance against illness, or any other plan of compulsory insurance which provides for medical service to be rendered contributors or their dependents, provided, controlled, or regulated by any state or the Federal government.

The Reference Committee also recommends the adoption of the following resolution:

Resolved, That the Council on Health and Public Instruction be instructed to investigate the relative adequacy of medical service and relations of the profession to the Public and report at the next annual session.

Respectfully submitted,

J. W. SCHERESCHESKY, Chairman,
A. T. MCCORMACK,
C. VAN ZWALENBURG,
L. H. TAYLOR,
C. ST. CLAIR DRAKE.

On separate motions, duly seconded and carried, each section of the report was adopted.

Dr. Arthur T. McCormack, Kentucky, then moved that the report of the committee be adopted as a whole.

Seconded and carried.

Resolutions on Medical and Surgical History of the World War

Dr. Gerald B. Webb, Colorado, Chairman, presented the following preambles and resolutions from the committee to which was referred the matter of publishing the medical and surgical history of the World War.

WHEREAS, The Surgeon-General of the Army has asked for an appropriation from Congress of \$150,000 to publish a medical and surgical history of the part played by the United States in the World War, and

WHEREAS, This appropriation has been approved by the Chief of Staff and the Secretary of War, and is now in the hands of the proper committee in Congress as a part of the Sundry Civil Bill, and

WHEREAS, The American Medical Association of some 83,000 members, of which a large proportion served in the medical services of the United States, is of the firm belief that the expenditure of this comparatively small sum would be much more than repaid in the benefits to the medical profession and to the public, and

WHEREAS, Many very valuable lessons were learned by the medical profession during the war, and it is feared that many of these will be lost unless this history is immediately published, and that failure to do this would have the unfortunate result of depriving the medical profession and the public of scientific, sanitary, surgical and medical information of the greatest value to their well being, and

WHEREAS, The value of a similar history has been well demonstrated in the publication of the medical and surgical history of the Civil War, although its appearance was regrettably delayed;

Resolved, That the American Medical Association earnestly urges that the sum in question be appropriated for the purpose stated and the publication of the volumes be expedited as quickly as possible. And be it further

Resolved, That copies of this resolution be sent to the Speaker of the House, Mr. Good, Chairman, of the Committee in Charge of the Sundry Civil Bill, to the Secretary of War, and to the Surgeon-General of the United States Army.

Respectfully submitted,

GERALD B. WEBB, Colorado, Chairman,
WALTER R. STEINER, Connecticut,
LEROY CRUMMER, Nebraska.

It was moved that the report be adopted.

Seconded and carried.

Dr. M. L. Harris, Illinois, moved that a copy of the report be sent to the secretary of each state and territorial medical association, so that constituent associations may add their influence in urging this matter before Congress.

Seconded and carried.

Report of Reference Committee on Legislation and Public Relations

Dr. J. H. J. Upham, Ohio, Chairman, presented the following report of the Reference Committee on Legislation and Public Relations:

The committee has considered the resolution introduced by Dr. W. G. Morgan, and desires to report as follows:

The unofficial data furnished in explanation of these resolutions are so astounding that the committee feels this is a matter for careful investigation by the Council on Health and Public Instruction, and if the facts discovered show such a deplorable condition to exist as indicated, that the Council be instructed to memorialize the proper congressional committees, urging the proper provision for adequate pay for medical officers.

The committee also recommends that the Council be empowered to send representatives to appear at hearings of congressional committees.

Respectfully submitted,
J. H. J. UPHAM, Chairman,
S. E. LAMBERT,
J. E. LANE.

It was moved that the report be adopted.

Seconded and carried.

On motion of Dr. James F. Rooney, New York, which was duly seconded, the House of Delegates adjourned until 2 p. m. Thursday, April 29.

Fifth Meeting—Thursday Afternoon, April 29

The House of Delegates met at 2 p. m., and was called to order by the Speaker.

Remarks by President Braisted

Admiral William C. Braisted, President of the Association, was introduced by the Speaker, and addressed the House as follows:

Mr. Speaker and Members of the House of Delegates: I have accepted the position of President of this great Association with the feeling that it was the Association's tribute to the splendid work of our Navy during the great World War. Let this be known as the Navy Year and let the same spirit of cooperation and harmony which characterizes the Navy when it is called to service for the country's sake be the actuating principle of our work this year, and let us lose no opportunity to make every effort to make practical use of the great health lessons of the war for the benefit of our people. I am here to work with you as a practicing physician and as a citizen of this great country, and not as Surgeon-General of the Navy, and with no personal or service motive. For months I have carefully considered the present condition of this Association from every standpoint, and feel that I have a fair grasp of the practical working of the organization. I have a feeling of fraternal and affectionate interest in every member and a supreme desire to use whatever opportunity or influence I may have for the best good of this Association in its great efforts for the good of the nation. I beg of you, therefore, to join with me this year in harmonious and disinterested effort for so laudable a purpose and hope in my address to you at our next annual session to be able to meet you with a smiling face and a feeling that we have made the most of the precious opportunities for doing good that are entrusted to us.

In union and harmonious effort there will be invincible power and splendid result.

In discord and self-interest there will be disintegration of the Association as a body and dismal and lamentable failure in every good effort.

At the close of President Braisted's remarks, the Speaker said: The House of Delegates desires to express its appreciation to you as the President of the Association, as Surgeon-General of the Navy, and as a physician. We thank you.

Dr. H. B. Gibby, Pennsylvania, Chairman, presented a supplementary report of the Reference Committee on Credentials, stating that 125 delegates had registered, were entitled to and had been seated in the House of Delegates.

The Secretary called the roll, and 118 delegates responded.

Dr. Arthur T. McCormack, Kentucky, moved that the reading of the minutes of the previous meeting be dispensed with. Seconded and carried.

Election of Officers

The next order of business being the election of officers, Dr. J. N. Hall, Colorado, nominated Dr. Hubert Work, Pueblo, Colo., for President of the Association.

The nomination of Dr. Work was seconded by Dr. William F. Campbell, New York; Dr. C. R. Woodson, Missouri; Dr. J. M. Aikin, Nebraska; Dr. William E. Anderson, Virginia; Dr. C. Van Zwalenburg, California; Dr. Arthur T. McCormack, Kentucky; Dr. J. Richard Kevin, New York, and Dr. H. N. MacKechnie, Illinois.

Dr. John D. McLean, Pennsylvania, nominated Dr. George E. de Schweinitz, Philadelphia, for President of the Association.

The nomination of Dr. de Schweinitz was seconded by Dr. L. M. Francis, Delegate from the Section on Ophthalmology; Dr. William F. Bacon, Pennsylvania; Dr. Thomas C. Chalmers, New York; Dr. Edward B. Heckel, Pennsylvania; Dr. Arthur J. Bedell, New York; Dr. James F. Rooney, New York; Dr. R. P. Sullivan, Delegate from the Section on Surgery, and Dr. A. E. Bulson, Indiana.

Dr. L. A. Yarborough, Tennessee, moved that nominations be closed. Seconded and carried.

The Vice Speaker appointed as tellers Dr. J. D. Brook, Michigan; Dr. A. B. Graham, Indiana, and Dr. Arthur J. Bedell, New York.

Dr. Work received the majority of the votes cast and was declared elected President of the Association.

Dr. John D. McLean, Pennsylvania, moved that Dr. Work's election made unanimous. Seconded and carried.

The Vice Speaker appointed Drs. John D. McLean, L. M. Francis, and J. N. Hall as a committee to find the President-Elect and escort him to the platform. President-Elect Work was escorted to the platform by the committee.

In response to cries of "Speech! Speech!" he said:

Mr. Vice Speaker, and Members of the House of Delegates: For sixteen years, as was stated here, I have been in this House each year in some capacity. Four times you have elected me to the office of Speaker of the House of Delegates. For four years you have borne with me and encouraged me and supported me, and have had some fun with me. Now, as the last act, you have elevated me to the highest position that can be given to a medical man in the United States. I would like to find language to express my appreciation to you men, but somehow I cannot find words to convey to you my heartfelt thanks for the distinguished honor you have conferred on me. (Applause.)

At this juncture, the Speaker resumed the chair.

The other officers elected are as follows:

Vice President—DR. ISADORE DYER, New Orleans.

Secretary—DR. ALEXANDER R. CRAIG, Chicago.

Treasurer—DR. WILLIAM ALLEN PUSEY, Chicago.

Speaker of the House of Delegates—DR. DWIGHT H. MURRAY, Syracuse, N. Y.

Vice Speaker of the House of Delegates—DR. F. C. WARNSHUIS, Grand Rapids, Mich.

Trustees—DR. CHARLES W. RICHARDSON, District of Columbia; DR. W. T. SARLES, Sparta, Wis.; DR. WALTER T. WILLIAMSON, Portland, Ore.

President Braisted nominated the following as members of standing committees, and the House of Delegates confirmed the nominations:

Judicial Council—DR. I. C. CHASE, Texas, five years.

Council on Health and Public Instruction—DR. MILTON BOARD, Kentucky, five years.

Council on Medical Education and Hospitals—DR. RAY WILBUR, California, five years.

Council on Scientific Assembly—DR. J. SHELTON HORSLEY, Virginia, to succeed himself for the term of five years; DR. F. P. GENGEBACH, Colorado, to serve until 1924. He further recommends that the terms of DR. E. S. JUDD, Rochester, Minn., and DR. ROGER S. MORRIS, Cincinnati, shall each be extended one year, so that they shall respectively expire in 1922 and 1923. To complete the personnel of the Council in accordance with the amended By-Laws of the Association to go into effect at the close of this annual session, he nominated DR. J. E. LANE, New Haven, Conn., for the term to expire in 1921.

Supplementary Report of the Council on Scientific Assembly

The Secretary presented the following supplementary report of the Council on Scientific Assembly:

The Council on Scientific Assembly recommends that the House of Delegates shall avail itself of its privilege to elect, on unanimous vote of the Council, more than three Honorary Fellows. In order that the Association may honor the guests of the National Examining Board and other eminent physicians in attendance on this Annual Session by electing them to honorary fellowship, it reports that the following eminent physicians have been nominated for honorary fellowship by several sections, and that these nominations have been approved by the Council:

Dr. Norman Walker, Representing the three Scottish Medical Corporations.

Col. H. J. Waring, M.S., F.R.C.S., Representing the Royal College of Surgeons of England.

Sir Humphry D. Rolleston, K.C.B., M.D., Royal College of Physicians, London.

Dr. E. E. Desmarest, Professor of Surgery, University of Paris, Paris.

Dr. Gustave Roussy, Professor of Medicine, University of Paris, Paris.

Dr. Jules Voncken, Liège, Belgium.
Dr. Iwaho Tsuchiya, Tokyo, Japan, Physician to the Imperial Court of Japan.

Respectfully submitted for the Council,
J. SHELTON HORSLEY, Chairman.

It was moved that the report be adopted and those nominated for honorary fellowship be elected. Seconded and carried.

Applications for Associate Fellowship

The Secretary then submitted applications for Associate Fellowship approved by the officers of the several sections.

On motion, duly seconded and carried, the Secretary was directed to cast the ballot of the House in those instances in which the applicant is eligible for Associate Fellowship in accordance with the provision set forth in the By-Laws, and when there is no objection to the applicant filed by the officers of the constituent association within whose jurisdiction the applicant resides.

Place of 1921 Annual Session

Dr. Frank Billings, Illinois, Secretary of the Board of Trustees, presented a supplementary report from the Board of Trustees, stating that invitations had been received to hold the next annual session of the Association in Boston, Saratoga Springs, Philadelphia, Washington, D. C., Indianapolis and Buffalo. These invitations were accompanied with letters of commendation from the commercial clubs from all of the cities mentioned with the exception of Boston. The invitation to meet in Boston came from the organized medical profession, and the invitation to meet there was extended by the Massachusetts State Medical Society, by the Suffolk County Medical Society, by the Harvard Medical School, and by Tufts Medical School.

The Board of Trustees was unanimous in recommending Boston as the next place of meeting. This approval of the Board of Trustees carried with it the suggestion to the House that the profession of Boston must give assurances to the Association that sufficient hotel accommodations will be provided. Furthermore, he called attention to the By-Laws, that in the event the place selected by the House of Delegates should appear to the Board of Trustees not to be suitable, the Board of Trustees was empowered to select another place for the meeting, provided it was done two months preceding the meeting.

On motion, duly seconded and carried, the report was adopted.

Resolutions from the Reference Committee on Legislation and Public Relations

Dr. J. H. J. Upham, Ohio, Chairman, presented the following resolutions for the Reference Committee on Legislation and Public Relations:

WHEREAS, The present governmental activities for the prevention of disease are inadequate to the needs of the nation; Therefore be it

Resolved: 1. That the House of Delegates of the American Medical Association reaffirms its position as favoring an adequate department of health with a cabinet officer at its head.

2. That the Council on Health and Public Instruction of the American Medical Association be instructed to request the Surgeon-General of the United States Public Health Service to designate three officers to act with the joint committee of the council, the state health officers, and the American Public Health Association, in conferring with the Senate Committee on Public Health and Quarantine and the House Committee on Interstate and Foreign Commerce in the preparation of a bill providing for a department of health, the nucleus of which shall be the United States Public Health Service.

3. That the President of the American Medical Association appoint two committees, each consisting of three Fellows who are affiliated with the Republican and Democratic committees and to attend the National Republican and Democratic conventions for the purpose of having written into both parties' platforms, planks favoring the establishment of a national department of health.

4. That the officers of the American Medical Association be instructed to bend every energy toward securing legislation providing for a national department of health.

5. That the Board of Trustees be requested to make such appropriations as may be necessary to carry out these resolutions.

For the Reference Committee on Legislation and Public Relations,
J. H. J. UPHAM, Chairman.

Dr. Arthur T. McCormack, Kentucky, moved that the resolutions be approved by the House by a rising vote and referred to the Council on Health and Public Instruction.

Seconded and unanimously carried.

Dr. John E. Lane, Connecticut, presented the following resolutions which were passed by the Section on Dermatology and recommended to the House for adoption:

WHEREAS, The deleterious effects of syphilis on the mortality and morbidity of the human race are so prevalent and so severe as to challenge the most serious attention of the entire medical profession; and

WHEREAS, In the scientific study of any disease, knowledge of its natural history is an item of cardinal importance; and

WHEREAS, Owing to the protracted course of syphilis, a continuous and complete clinical record of a given case can be secured only through the services of several successive medical observers; and

WHEREAS, It is highly desirable that a sufficient number of completed histories be accumulated and preserved and made easily accessible to students; and

WHEREAS, For the successful accomplishment of the purpose set forth above, the interest and cooperation of a considerable number of the best elements of our profession as represented in the membership of the American Medical Association are necessary; therefore be it,

Resolved (1) That the Section on Dermatology of the American Medical Association recognizes the importance of ascertaining the natural history of syphilis and of making this history accessible and in form serviceable to students of medicine; further

Resolved, (2) That the Section on Dermatology of the American Medical Association respectfully requests the trustees of the American Medical Association to appoint a committee from the sections most immediately concerned, whose duty it shall be to devise practical means and methods of accomplishing the foregoing specified purpose; and further

Resolved, (3) That the representatives of this section in the House of Delegates be requested to present these preambles and resolutions to the House of Delegates, and to ask its endorsement.

It was moved and seconded that the resolutions be adopted. Carried.

The Secretary stated that the foregoing preambles and resolutions came regularly into his hands and had been referred to the Reference Committee on Hygiene and Public Health.

Report from the Reference Committee on Hygiene and Public Health

Dr. J. W. Schereschewsky, Chairman of the Reference Committee on Hygiene and Public Health, then reported as follows:

The committee reports back the resolutions submitted from the Section on Dermatology with the recommendation that they be approved by the House and referred to the Council on Health and Public Instruction for action.

(It was moved and seconded that the recommendation of the Reference Committee be concurred in. Carried.)

RESOLUTION CONCERNING MIGRATION OF INDIGENT CONSUMPTIVES

WHEREAS, The National Tuberculosis Association, through investigations of its Committee on Indigent Migratory Consumptives, covering the last fifteen months, has found:

That there is a large migration of indigent consumptives to the Southwest in search of health;

That out of 1,786 cases, largely indigent or potentially indigent, reported from the Southwest in the last six months, 738, or 41.3 per cent., had been definitely advised to go there by physicians;

That this migration of indigent and potentially indigent consumptives is ill advised in that it causes much needless suffering and loss of life brought on by inadequate care, worry, homesickness and lack of proper food, which are conditions too frequently experienced after arrival; and, furthermore,

That the migration of this group is a menace to the public health, both during migration and after arrival, and is a financial drain and social burden to the communities to which the migration goes. Therefore, be it

Resolved, That in order to check this unnecessary and undesirable migration, physicians throughout the country be not only requested but urged not to advise their tuberculosis patients to migrate to the health resort states, unless such patients have sufficient funds to properly provide for their necessary care and comforts for at least one year.

AMENDMENT TO THE FOREGOING RESOLUTION. Resolved, That the Section on Preventive Medicine and Public Health hereby requests the House of Delegates to instruct the Council on Health and Public Instruction to investigate and report on, at the next annual session, the migration of consumptives from one state to another throughout the Union and the number of indigents so foisted on one state by another, and report definite suggestions to prevent this constant undesirable migration.

The Reference Committee on Hygiene and Public Health reports back the foregoing resolution with the recommendation that it, as amended by the Section on Preventive Medi-

icine and Public Health, be approved by the House and be referred to the Council on Health and Public Instruction.

(It was moved and seconded that the recommendation of the committee be concurred in. Carried.)

RESOLUTION ON SALE OF ENDOCRINE PREPARATIONS

At the last Annual Meeting of the Surgical Section of the Medical Society of the State of New York, the following resolution was passed:

WHEREAS, The promiscuous use by the laity of preparations of the glands of internal secretion has led to manifest harm; and

WHEREAS, The uncontrolled use of potent glandular derivatives carries with it the danger of self-medication, be it

Resolved, That the Surgical Section earnestly request that the American Medical Association take the necessary steps to prevent any endocrine preparation being sold to the public except on a physician's prescription.

The Reference Committee on Hygiene and Public Health endorses the principles embodied in this resolution and recommends that the House of Delegates instruct the Council on Health and Public Instruction to investigate the matter in cooperation with the U. S. Public Health Service and report with appropriate recommendations at the next annual session.

(Dr. Arthur T. McCormack, Kentucky, moved the adoption of the resolution. Seconded and carried.)

RESOLUTIONS ON LEPROSY

The following resolution has been submitted by the Section on Preventive Medicine and Public Health:

WHEREAS, Leprosy is a national menace.

Resolved, That the House of Delegates be requested to ask the American Public Health Association to call a national conference to discuss every phase of the problem to the end that the public may be educated to the insidious spread of the disease, the possibility of cure or arrest in the earlier stages of the disease, and the necessity of segregation.

The Reference Committee on Hygiene and Public Health reports favorably on this resolution and recommends its approval by the House of Delegates.

(Dr. Arthur T. McCormack, Kentucky, moved that the resolution be referred to the Council on Health and Public Instruction with power to act. Seconded and carried.)

RESOLUTION OF THE SECTION ON PREVENTIVE MEDICINE AND PUBLIC HEALTH

The Reference Committee reports favorably on the following resolution regarding the selection of a site for a national leprosarium, and recommends that the matter be referred to the Council on Health and Public Instruction:

Resolved, That the board charged with the responsibility for selecting a site for a national leprosarium be requested to convene at the earliest possible moment and arrive at a decision as between the various sites offered; and that the Surgeon-General of the U. S. P. H. S. be urged immediately thereafter to establish said national leprosarium as provided by Congress.

(Dr. Frederic E. Sondern, New York, moved that the recommendation of the committee be concurred in. Seconded and carried.)

Resolution of the Reference Committee on Hygiene and Public Health

The Reference Committee on Hygiene and Public Health presents the following resolution and recommends its adoption:

Resolved, That the American Medical Association commend the activity of the U. S. Public Health Service and the several state health departments in the treatment and prevention of trachoma.

(On motion, duly seconded and carried, this resolution was adopted.)

Submitted for the Reference Committee,

J. W. SCHERESCHEWSKY, Chairman.

(Dr. W. E. Anderson, Virginia, moved that the report of the Reference Committee on Hygiene and Public Health be adopted as a whole. Seconded and carried.)

Report of Reference Committee on Reports of Officers

Dr. Thomas S. Cullen, Maryland, Chairman, presented the following report of the Reference Committee on Reports of Officers:

The several reports referred to this Reference Committee have been considered by the committee, which submits the following report.

REPORT OF SECRETARY

From the Secretary's Report, we learn that the membership in the state societies totals the astonishing number of 83,338 physicians, and that the Fellowship of the American Medical Association consists of 47,045 members. There has been a net gain of 1,633 Fellows during the year.

The Secretary chronicles the death of Dr. Emery Marvel of Atlantic City, Second Vice President of the Association, and the brother of Dr. Philip Marvel, Chairman of our Board of Trustees.

The Secretary also announces the death of Dr. Elmer Ernest Southard of Cambridge, Mass., Chairman of the Section on Nervous and Mental Diseases.

In the section devoted to organization, the Secretary gives a timely warning. "There is a possible danger which should be guarded against—namely, a multiplicity of organizations in the same territory having practically the same objective. Whenever an unnecessary new organization in an already occupied territory is effected, there is always the danger that rivalry will result between the two organizations which consciously or unconsciously will interfere with the effectiveness of the organization of the medical profession in that locality."

Your committee would like to emphasize the Secretary's warning.

The Secretary's report is short, but contains much valuable information.

REPORT OF THE BOARD OF TRUSTEES

Your committee has read with much interest the report of the Board of Trustees, and wishes it were possible for each member of the Association to have the opportunity of visiting the Association Headquarters, with its numerous Council and bureau headquarters, and to watch the printing of THE JOURNAL and of the monthly medical publications of our Association.

When it is realized that the total gross income for the year was nearly \$800,000, one gathers some idea of the stupendous task the Editor and General Manager and the Trustees have before them.

One of the most striking things in the report is the publication of the Spanish edition of THE JOURNAL. The subscription list at the end of 1919 totaled 2,908. As mentioned in the report, this venture "was undertaken at the request of the International Health Board of the Rockefeller Foundation, which agreed to pay half the loss. The actual loss to the Association to date has been less than \$10,000, which amount promises to be returned with more than gratifying results within the first five-year period of its publication."

The committee feels that this carrying of the Association publication to all parts of South America and to other Spanish speaking countries will be of inestimable value and further, that it will be a most potent factor in cementing the already very cordial relations existing between these countries and the United States.

Your committee was also impressed with the excellent circulation and financial showing made in the publication of the special journals. It noted with interest that the ARCHIVES OF SURGERY will make its initial appearance in July. The QUARTERLY CUMULATIVE MEDICAL INDEX is of great value to the medical profession, and your committee was pleased to learn that notwithstanding the amount of labor and expense in its publication, the loss was less than \$2,000.

A perusal of the Trustees' Report, "Cooperation of the Pharmaceutical Houses," is well worth the time of every member of the profession, and your committee would emphasize the statement of the trustees: "The Council, constituted of scientific men, working without remuneration in the interest of scientific medicine and the medical profession expects—and rightfully—the cooperation and support of the members of that profession. What is needed, therefore, is the active, sympathetic cooperation of physicians; the cooperation of pharmaceutical houses will follow as a matter of course."

Your committee would go still further and move that a vote of thanks of the House be extended to those scientific men who have devoted so much valuable time to the welfare of the Association.

The paragraph dealing with the Propaganda Department is most enlightening. It is doing a wide and varied work. The trustees say of it: "As a clearing house for information on the subjects with which it deals, it proves a boon alike to the profession and the public."

In the paragraph entitled "Increased Expenses," the trustees say: "The steadily increasing cost of production is likely to cause serious concern if it continues much longer." They then give a detailed report of the increased cost.

From a perusal of the Trustees' report, it is perfectly evident that they are exercising just as much care and judgment as they would if handling their own individual affairs, and the members of the Association may, with confidence, abide by their fidelity to their trust.

The Board of Trustees recommends that the House of Delegates direct the Council on Medical Education and Hospitals to substitute the term "Approved Hospitals" for that of "Standardized Hospitals" in its official reports and publications.

In this, your committee heartily concurs.

ADDRESS OF DR. ALEXANDER LAMBERT, PRESIDENT OF THE
AMERICAN MEDICAL ASSOCIATION, TO THE
HOUSE OF DELEGATES

Your committee read with much interest the President's sketch of the gradual evolution of the hospital from its beginnings until the modern hospital resulted, and were surprised and gratified to learn that nearly all the large associations in any way related to hospital management, nursing and the medical and surgical care of the sick were getting together to take stock of existing conditions, and to formulate plans for the betterment of hospitals and for the more adequate care of the sick entering their institutions.

The President in his address said: "The subject is of such great and constantly increasing importance to the medical profession that it is time the American Medical Association should take cognizance by special action of a subject of such vital interest to its members, and should lend its support and influence through definite and continued action."

That the Association has appreciated the importance of this matter is indicated in the report of the Board of Trustees, which says: "At the meeting of the Association in Atlantic City, in 1919, the House of Delegates adopted the following resolution, which was presented by the Reference Committee on Reports of Officers:

"That the Trustees be instructed to establish a Council on Hospitals as an independent body, or a Bureau on Hospitals as a body subsidiary to one of the already existing councils, the details of the organization to be left to the trustees with power to act."

The Trustees further say, "In conformity with the statements made above, the board recommends to the House of Delegates the change in name of the Council on Medical Education to the "Council on Medical Education and Hospitals."

"In view of the fact that no existing organization has the legal power to standardize hospitals, therefore: The board recommends that the House of Delegates direct the Council on Medical Education to substitute the term 'Approved Hospitals' for that of 'Standardized Hospitals' in its official reports and publications."

This House of Delegates at its meeting on Tuesday, April 27, changed the name of the Council on Medical Education to that of the "Council on Medical Education and Hospitals."

As pointed out in detail, in the Trustees' report, the Council on Medical Education has a vast amount of valuable data relative to the hospitals of the United States. This was gradually accumulated, as in the medical centers the hospitals and medical schools were of necessity so intimately associated, the one with the other, that in such instances it was essential to gather full data relative to the hospital at the time the medical school was inspected. These data will be of great value to all those associations engaged in this splendid work.

The Board of Trustees, also, is greatly interested in the furtherance of the work, and will do all in its power to make easy the task of the Council on Medical Education and Hospitals.

We are deeply indebted to Dr. Lambert for having made this important question the subject of his address to the House of Delegates, and we are more than pleased that this House has so promptly ratified the request of the trustees and set the necessary machinery in motion.

That the Council on Medical Education and Hospitals next year will have much to say on approved hospitals, we have no doubt whatsoever.

REPORT ON THE ADDRESS OF THE SPEAKER OF
THE HOUSE OF DELEGATES

The recommendations of the Speaker relative to the Ad-Interim Committee and to the method of nominating the standing committees have already been acted on by the House of Delegates, and hence need not be considered here.

His suggestion that it might be advisable to reduce the number of the trustees to seven or to five members and subdivide the United States into trustee districts, is worthy of serious consideration. Your committee feels that the number of trustees might well be reduced to seven, and would suggest that the recommendation of the Speaker be given serious consideration by the House at the next annual session, and that the matter be at once referred to the Judicial Council, in order that it may report a concrete proposition at the next session.

Your committee also feels that it would be well for the House of Delegates, next year, to consider the Speaker's suggestion that each section unit of the Scientific Assembly should indicate, by nomination to the House, those whom they would approve for the Presidency and Vice Presidency. This, as the Speaker has well said, "will put before the House many potential presidents for consideration, both for immediate and subsequent elections."

Your committee endorses most emphatically the Speaker's suggestion relative to the establishment of a separate governmental department of public health, and urges on this House the wisdom of at this time placing itself squarely behind the movement looking to the speedy establishment of a cabinet office devoted solely to health matters, and presided over by a member of the medical profession.

In order that this matter may receive immediate consideration, we recommend that the Council on Health and Public Instruction be requested to study the subject carefully from every angle, and then to enlighten the entire membership of the Association as to the best means of securing the establishment of this cabinet physician.

Your committee fully concurs in what the Speaker has said relative to compulsory military training, and feels that the House of Delegates of the American Medical Association should place itself on record as being in thorough accord with the principle of compulsory military training.

Your committee read with the keenest appreciation the beautiful tributes of the Speaker to the memory of our departed colleagues, Floyd M. Crandall, C. E. Cantrell and Clinton P. Meriwether, and would respectfully suggest that copies of these tributes be sent to the families of these "three upright, tried and true physicians."

Your committee feels that this is the time and place to express, on behalf of the House of Delegates, our deep appreciation of the masterly way in which our Speaker has guided the deliberations of the House. He has been the only Speaker that the House has ever had; he has conducted the business of the House with justice and dispatch, and with an understanding and kindness that could not be excelled, and his rare sallies of wit have smoothed out many difficulties. On behalf of the House, we can truly say, There is only one Hubert Work.

THOMAS S. CULLEN, Chairman,
F. B. LUND,
HOLMAN TAYLOR,
B. R. MCCLELLAN,
C. R. OGDEN.

The report was considered section by section, and on separate motions, duly seconded and carried, was adopted.

Dr. Thomas S. Cullen, Maryland, then moved that the report be adopted as a whole.

Seconded and carried.

Resolution of Thanks to Senator Owen

Dr. Oscar Dowling, Louisiana, asked unanimous consent, which was granted, to introduce the following resolution:

WHEREAS, The American Medical Association has repeatedly and consistently advocated the establishment of a Department of Public Health, and

WHEREAS, Senator Robert L. Owen, of Oklahoma, has wholeheartedly supported this proposition and made every possible endeavor to cause the enactment of a law creating a department, be it

Resolved, That the American Medical Association tenders to Senator Owen a vote of thanks in recognition of genuine service to humanity.

It was moved that the resolution be adopted.

Seconded and carried.

Supplementary Report of the Council on Health and Public Instruction

Dr. Milton Board, Kentucky, member of the Council on Health and Public Instruction, presented the following resolution, which was adopted April 28, 1920, by the Council on Health and Public Instruction:

WHEREAS, The House of Delegates of the American Medical Association, at the 1917 session at New York, adopted a resolution declaring that alcohol was not a stimulant, nor a food, and was of little if any value as a drug for internal administration, and

WHEREAS, The statement was made during the recent epidemic of influenza that whisky was necessary in the treatment of this disease, and that avoidable suffering and death was resulting through lack of whisky for this purpose.

Resolved, That the House of Delegates of the American Medical Association reaffirms the resolution adopted in 1917, and further records its opinion that whisky is not necessary for the proper scientific treatment of influenza.

It was moved and seconded that the resolution be adopted.

After discussion by Drs. C. Van Swalenburg, California; Arthur T. McCormack, Kentucky; James F. Rooney, New York; Charles J. Whalen, Illinois, and Randolph Winslow, Maryland, which brought out the opposition of certain of these speakers to any action which might be construed as imposing on the physician inability to prescribe what he thinks is necessary in the treatment of his patient, a motion was made by Dr. J. H. Wilson, Pennsylvania, that the resolution be tabled.

Seconded and carried.

Telegram on Tuberculosis from Surgeon General, U. S. P. H. S.

The Secretary asked unanimous consent, which was granted, to read the following telegram from the Surgeon General of the United States Public Health Service:

Washington, D. C., April 27, 1920.

President, American Medical Association,
New Orleans, La.

I desire to urge more active participation by the general practitioner and by general hospitals in treatment of tuberculosis to insure earlier diagnosis, properly trained interns and other personnel to popularize treatment in the home climate, and to provide additional facilities. I earnestly endorse the resolution passed by the National Tuberculosis Association in 1916, recommending that general hospitals should admit tuberculosis patients and provide separate wards for that purpose. Sanatoriums and specialists in tuberculosis will always be needed and we should have more of them, but I believe that success in the antituberculosis campaign is largely dependent on, first, convenient facilities for observation and prompt treatment of patients with open tuberculosis; and second, in a sharpened perception and higher degree of skill by which the family doctor will make an early diagnosis or even forestall the development of clinical tuberculosis in the adult before a definite diagnosis is possible; to provide adequate care for tuberculous ex-service men and others, and protect infants from infection. Enlist the aid of the general practitioner, allay phthisophobia, and improve home treatment of tuberculosis. The opening of general hospitals to this most common of all serious diseases will materially assist.

CUMMING, Surgeon General, U. S. P. H. S.

It was moved that the telegram be referred to the Board of Trustees, specifically empowering that body, at its discretion, to retransfer the subject matter or any part thereof

Seconded and carried.

Appreciation of Hospitality at New Orleans

Dr. M. L. Harris, Illinois, moved that the American Medical Association, through its House of Delegates, express by a rising vote its great appreciation of the extremely gracious manner in which the medical profession, the charming ladies, and hospitable citizens of New Orleans and Louisiana have entertained the Association and its guests during this session.

Seconded and unanimously carried.

On motion of Dr. John E. Lane, Connecticut, the House of Delegates adjourned.

ADDENDUM**Report of the Committee on the Narcotic Drug Situation in the United States**

At the present time the people of the United States are awake as never before to the menace of the narcotic drug situation. This situation was made acute by the activity of the federal authorities acting under recent decisions of the U. S. Supreme Court, which decisions interpreted the Harrison Narcotic Law as applied to the practice of medicine. Under the social pressure exerted by the demand for facts and guidance, the medical profession should take the lead to which their position entitles them, and should not be compelled to follow in the wake of the great work already begun of stamping out drug addiction. That such a demand is not too radical or sensational is indicated by the fact that the narcotic drug habit is declared a "pestilence" by the New York City Board of Health in a recent amendment to its Sanitary Code. The profession has already responded to the situation by the appointment of committees for investigation in the hope of answering some of the most pressing questions. It is after a year of investigation, of conference, and of study that the committee appointed by the American Medical Association presents the following report.

There are certain preliminary questions which will be asked in some form by one who approaches the problem of drug addiction in a constructive attitude. These may be stated in the following form:

1. Can the use of narcotics as we now know it be said to be a "modern" problem?
2. Is there proof that drug addiction is widespread enough to constitute a social menace?
3. Is there genuine danger of an increase of drug addiction in proportion to the population?
4. What measures have been taken to meet the danger of drug addiction as it now exists? How far do these measures meet the present situation?
5. In what direction should the measures now employed in the treatment of drug addiction be extended?

We shall undertake to point out in this report that drug addiction in the sense in which we ordinarily use the word at the present time is a modern problem; that for certain reasons connected in part with commerce and the spread of civilization it is widespread; and that because of the growth of cities with their close association, as well as because of the ease of communication, there is grave danger of the rapid increase of the drug habit unless we take advantage of the present interest and get control of the situation through law and the care of those already victims and therefore centers of imitation-suggestion. We shall review in the words of men who know from actual experience with large numbers of cases the measures taken to meet the menace, and on the basis of conclusions from these facts shall recommend future action.

1. The poppy plant and its qualities were known throughout the Mediterranean basin at an early period. It is mentioned in the poetry of Homer and the words of Hippocrates. That such knowledge followed the travel routes of the ancient world is beyond question. But the use of opium to any great extent in the East, in India and China, seems to coincide with the spread of Mohammedanism and with the ban of Islam on alcoholic beverages. The use of the pipe and the custom of chewing spread rapidly from this period until the Chinese government took measures to stop it. The soil of India was peculiarly adapted to the growth of the poppy, where it early became an article of commerce as well as a government monopoly. In 1757, this monopoly passed into the hands of the East India Company, and from that company to the British government.

We have few facts to indicate that drug addiction came to notice as a menace among Western peoples until after the discovery of the opium alkaloids, particularly morphin, and after the perfecting of the hypodermic syringe. In 1855, Dr.

Wood of Edinburgh advised the introduction of morphin by incision. It was only fifty-four years ago that the injection of morphin under the skin was introduced into France. While we know that opium smoking was known, particularly to those in touch with the East, still in general the effects of opium smoking are less deleterious than those of morphin. Moissan¹ shows that the smoke of opium contains only a trifling amount of morphin. "The effect is apparently due, not to that alkaloid, but to such decomposition products as pyrol, acetone and pyridin, and hydropyridin bases." Browne² found that after smoking an opium mixture containing 9.98 per cent. of morphin, 7.63 per cent. was left in the dross, so that only 1.35 per cent. of morphin was carried over in the smoke or decomposed by the heat.

Still more recent than the use of morphin with the hypodermic needle is that of cocain and of heroin, now perhaps the greatest drug menace of city life. Heroin has been in use only about twenty years. The ease with which these drugs can be used as snuff ("happy dust"), and their recent use by gangsters, make this a separate problem. Already physicians are distinguishing morphin and heroin users as distinct types. We shall see the evidence in the reports incorporated herewith.

The facts stated indicate that we are not dealing with the opium smokers or eaters of another age and civilization, but with a problem which in one phase dates back to the middle of the nineteenth century with the introduction into use of the hypodermic needle. In another phase, heroin addiction dates back not more than ten years. As it is a recent problem, small wonder that we find the facts not classified. To those who know the facts regarding the rapid spread of the drug habit among the population, there seems serious basis for alarm.

2. When we attempt to answer in terms of fact the question of the extent of the use of narcotic drugs, we are surprised at the inadequacy of our information. If we turn to commercial statistics, we find that it is only very recently that the extent of the commerce in these drugs could be estimated. Laws and regulations governing their sale and use did not provide for tracing them from the importer to the ultimate consumer. But tables compiled from the registrations under the Harrison Narcotic Law and published in a report on the "Traffic in Narcotic Drugs," made by the Treasury Department of the United States under date of June, 1919, give some idea of the ramifications of the traffic. These tables showed the use by manufacturers in 1914 of 118,282 pounds of opium and of 767,283 ounces of morphin, heroin and cocain, in the order named. Of 4,092 manufacturers making proprietary medicines, 1,098 reported the use of either opium, morphin, heroin or cocain in their preparations. It has been estimated that fully 90 per cent. of the opium entered for consumption is used for other than medicinal purposes.

The system of registrations required by the Harrison Narcotic Law showed a total of 233,491 registrations—125,905 physicians, 42,240 dentists, 10,399 veterinarians, 48,196 retail dealers, 3,799 hospitals, 76 importers, and 831 wholesale dealers. This list gives some idea of the range of legitimate dealing with drugs. In addition, there is of course the large amount of smuggling from Canada and Mexico in addition to that possible from our own long coast line on the two oceans and the Gulf of Mexico. Even on the basis of what is known, the astounding fact is revealed that enough opium is consumed in the United States to provide every man, woman, and child with thirty-six doses a year on the estimate of 1 grain to a dose. When we contrast this with an annual per capita consumption in Austria of one-half grain; in Italy of 1 grain; in Germany of 2 grains, and in France of 3 grains, we have some concept of the appalling extent of the use of drugs in the United States.

Probably the most serious attempt to determine the extent of drug addiction among the population was attempted by the compilers of the report of the Treasury Department to which we have referred. Five sets of questionnaires were issued. No. 1 was sent to the chiefs of police of 1,263 cities of the United States having a population of more than 5,000. Out of 760 replies, 372 reported no data. No. 2 was sent to 3,271 wardens of state, county and municipal prisons and reformatories. Of the 760, only 126 contained certain information. No. 3 was sent to 2,464 superintendents of state, county and municipal almshouses, 584 to superintendents of state hospitals, 471 to superintendents of insane asylums, and 1,582 to county and municipal hospitals—a total of 5,101

institutions. Replies were received from 1,520, about 30 per cent. of the the number. No. 4 was addressed to 3,023 state, district, county and municipal health officers. Of the 983 replies received, 777, or 26 per cent., contained information of value. No. 5 was sent to 4,568 superintendents of private hospitals and sanatoriums. Only 227 returned information of any value. It will be seen from the most casual glance at the percentage of returns that they can have very little statistical value. When we subtract from those returned with something definite in the way of numbers the inevitable wastage from inexactness and carelessness, it is probable that 20 per cent. of the total possible amount of information would be a liberal estimate of the returns from this questionnaire. The most valuable result of the attempt was to show in a startling way the lack of proper records and reliable statistics as to drug addiction.

3. Estimates as to the number of drug addicts in the United States vary from 200,000 to 4,000,000. For reasons already stated, we distrust estimates based on the questionnaire material quoted above. If we estimate from the compulsory registration of narcotic drug addicts in the Greater City of New York district in force since July, 1919, we should find that there had been 7,741 registrations. But this is believed to be considerably less than the whole number resident in this district. In view of New York's transportation problems and traffic dangers, it gives us pause to find that 23 per cent. of 3,500 registered addicts were chauffeurs, motormen and drivers. Such a fact in itself shows the menace of the drug problem.

From the facts we have thus far presented, the extent of the use of drugs in the United States is proved more by the amount of legitimate commerce in them than by exact statistics as to the number of addicts. But the figures concerning this commerce speak for themselves. It is, however, well to remember that after our entry into the European conflict there was created in this country what was known as the War Trade Board. One of the duties of this board was to restrict the importation and exportation of merchandise to actual necessities. Opium and its alkaloids, also coca leaves and cocain were among the items restricted. Although this board has gone out of existence, certain functions performed by it are still in force and are performed by other departments. Decisions relative to the importation of narcotic drugs are now being made by the State Department. It is still true that England permits the exportation to this country of the drugs mentioned in the Harrison act only in cases in which the importer has obtained permission to import these drugs from the State Department.

4. The recognition of drug addiction as a national problem can be said to date from the passage of the Harrison Narcotic Law in 1914. In general, the scope and purpose of this law appear to be "a regulation of the distribution of narcotic drugs, and the limiting of their consumption by human beings to cases where they are administered, prescribed or dispensed to a patient by a physician or dentist." Another purpose, as later declared by the Supreme Court, was "to prevent the possibility of narcotic drugs being illegally disposed of without payment of the tax and without the use of order forms." The drugs covered are specified to be "opium or coca leaves, or any compound, manufacture, salt, derivative or preparation thereof," and the persons entitled to register and required to pay a tax are limited to importers, manufacturers, producers, dealers, physicians, dentists, veterinary surgeons, and other practitioners permitted by some of the states.

State governments may impose restrictions and regulations governing the control of narcotic drugs, which, however, should be in conformity with the federal Harrison Narcotic Law. The present narcotic drug law in force in the state of New York, known as the Whitney Law, was framed with the idea of permitting the ambulatory treatment of addicts. "Ambulatory" treatment is the giving of a narcotic drug into the possession of an addict for self-administration. As the law now stands, it imposes on the entire medical and pharmaceutical professions a mass of annoying and petty restrictions and requirements which were thought to be necessary in order to prevent the abuse of the ambulatory method of treatment, which so temptingly lends itself to questionable practices by addicts and others. The whole weight of opinion is now against this method of treatment. It therefore seems unjustifiable to insist that reputable practitioners shall be inconvenienced by the necessity of familiarizing themselves with the technical requirements of two sets of laws and regulations not in harmony. When there is uniformity regarding treatment, classification and after-care of addicts,

1. Moissan, H.: *Compt. rend.* 4: 33 (Dec. 5) 1892, quoted from *Encyclopaedia Britannica*, Ed. 11.
Browne, F.: *Report on Opium*, Hong-Kong, 1908.

a long step will have been taken toward unification of state laws in harmony with the federal law.

CONFERENCES ON DRUG ADDICTION

In order to cover more fully the questions asked at the beginning of this report, particularly with reference to the treatment of addicts, the chairman of the committee held many conferences during the year in New York, Chicago, Washington, Philadelphia and Atlanta.

The following statements were taken from notes made at the several conferences. Those who revised the notes of their statements or furnished new statements are here quoted.³

CONCLUSIONS

As we review the testimony and experience of these physicians and officials who have dealt with thousands of drug users of all types of intelligence and character, it becomes evident that there is a high degree of agreement on the essential points. The main point, and the one on which all agree, is to get the patient off the drug as soon as possible. Whether this is to be done at once, or within a week, the sooner over, the better for the patient.

There was astonishing unanimity among those who took part in the conference as to the evil effects of the "ambulatory treatment," the giving of a narcotic drug into the possession of an addict for self-administration, with no control over the number of physicians furnishing a supply. This method of treatment is proved a failure, and there was agreement that it should be forbidden.

We think it is also apparent that the habitual users of narcotic drugs may be divided into two classes. In Class 1 we shall place all those who suffer from a disease or ailment requiring the use of narcotic drugs, such as cancer, and other painful and distressing diseases. Patients in this class are legitimate medical cases, and the physician should be ever mindful that his patient should protect him by not sharing the drug with others.

After excluding Class 1, we have left for consideration those who are addicts—those who use narcotic drugs for the comfort they afford and continue their use solely by reason of an acquired habit. In this class we have those who are suffering from a functional disturbance with no physical basis expressed in pathologic change.

We find in an article reviewing the literature dealing with the increased tolerance and withdrawal phenomena in chronic morphinism, by Dr. A. G. DuMez⁴ of the United States Public Health Service, this statement: "The only knowledge of a positive nature that we really have at present concerning these problems is that . . . there is evidently present in the blood serum of tolerant animals (dogs) during periods of abstinence a substance or substances which, when injected into normal animals of the same species, causes the appearance of symptoms identical with the so-called withdrawal phenomena."

We cannot object to Dr. DuMez picking this choice bit of lonely literature for a place in his conclusion; but we do object to the phrase introducing it: "The only knowledge of a positive nature that we really have at present concerning these problems is that, etc."

In a reply to a letter calling his attention to this phrasing, Dr. DuMez wrote under date of March 17, 1920: "In my opinion, however, that portion of the concluding paragraph which states, 'And there is evidently present in the blood serum of tolerant animals (dogs) during periods of abstinence a substance or substances which, when injected into normal animals of the same species, cause the appearance of symptoms identical with the so-called withdrawal phenomena,' has not been conclusively proven." A word to the wise is sufficient.

We turn to the consideration of the persons classified as addicts after excluding all those who suffer from a disease calling for the use of narcotic drugs, and with the conviction that we are dealing with functional conditions for which the remedy is the withdrawal of the drug. On the basis of the testimony we have submitted in this report we suggest

the following subdivisions of Class 2, in which we include addicts as just defined:

1. Correctional cases.
2. Mental defectives.
3. Social misfits.
4. Otherwise normal persons.

Such a classification as the one just suggested would aid in the solution of one of the most pressing problems connected with the treatment of drug addicts—the problem of after-care. All the testimony of those present at the conference agreed that if the addict is permitted to return to his old surroundings before he is built up physically, mentally and morally, a discouraging number return to the drug habit. But if they could be studied in an institution of mental and physical hygiene after they are taken off the drug, this result could in many cases be prevented. The correctional cases should be committed to institutions with no age limit—from the cradle to senility, if necessary. If they show marked improvement, they could be put on probation under the care of a technically trained person acting as probation officer. With defectives, institutional care must be provided where they can be comfortable and often self-supporting, but where they shall not be permitted to reproduce their kind. As to the social misfits and the otherwise normal, inasmuch as up to the present no completed treatment in the way of analysis and therapy has been provided, we shall devote the succeeding paragraphs to a consideration of what can be done for these classes of addicts.

THE PROBLEM OF THE SOCIAL MISFIT

When one finds himself in a situation to which adjustment and adaptation seem almost hopeless, there are two courses open. He can use his energy and initiative to alter the environment; or he can seek escape from the grim reality of the situation in an inner change. The adolescent often seeks escape in day dreams of a future which can be realized. For many emotional persons, religion, with its esthetic forms and duties, gives relief. Another class, sometimes because of constitutional inferiority, again perhaps because the situation is really hopeless, develops a neurosis or psychosis. Many geniuses belong to this class. Just why others under the same stress "neither wince nor cry aloud" may not be because of sturdy ancestry makes for stability; it may be that life has not given that which constitutes a terrible experience.

The social misfit has become much more of a problem with the development of individualism and rationalism. An earlier world accepted unhappiness and disease with resignation as the hand of Providence. Strangely enough, with the accumulation of an economic surplus and shortened hours of labor has come the problem of getting into the right place to enjoy the surplus and the leisure. Unremitting toil and consequent deadened nerves prevented such problems as arise with the change from a "pain economy" to a "pleasure economy," so that it may be said that a society which has enough of a surplus for leisure will also have more misfits. This is shown by the fact that these misfits are found in all social strata.

It is within a generation that a drifting industrial population with its enormous labor turnover has brought home to the commercial world what an expense on business is the social misfit, who is also an economic misfit; for the restlessness of inner life works its way out in drifting from job to job, listening to any agitator who assures him that this dissatisfaction and restlessness are the fault of some one, besides himself. The studies of strikes made by men like Carlton Parker and Ordway Tead have brought it home to us that the basal instincts must be satisfied if organized society is to last. We know that the misfit can no longer be ignored. He is too numerous; he has learned the lesson of organization; and he has learned through association means of cheap satisfaction that deaden for a time his elemental cravings, even though they return him to society more of a menace and a care than before.

Both because society grows more humane and because the social sciences have taught us that humaneness has a practical bearing on group success, we are asking ourselves today why we have such numbers of misfits in society; men and women.

3. The individual statements are included on a reprint of this report, which will be sent on receipt of a stamped addressed envelop.

who find their living conditions intolerable; who will seek refuge in the cheap and transient relief of drugs. Since modern psychology has taught us the importance of the infantile patterns in later life and of the life-long influence of early education, we have turned to scrutinize more closely just what our so-called democratic education has done to make life happier and more successful for the masses.

Even before the great war, earnest educators like Madame Montessori and Professor Dewey had been calling attention to the fact that our educational system was an anachronism: perfected in the cloister; disciplinary in character; made to fit a life of cultured leisure; teaching almost nothing of the life into which the child must go at the completion of his school life. With the older apprenticeship system destroyed by the minute subdivision of labor of the modern factory system, the child left the school to go to a factory where he learned some small process, often a "blind alley." When the terrible monotony of the process drove him out, there was some other minute process waiting for him in some other factory—no vision of what it all meant, of his work as a part of the whole. Thus, he marries, burdens himself with family cares, and becomes tied to the process. If he has "nerves," some day he will get a nightmare vision of himself as a piece of social wastage, a victim of conditions far more far-reaching than his individual life. When he becomes organized and vocal, society awakens to the fact that he is an I. W. W., a bolshevik, or what not. He is not wholly to blame.

Modern psychology pictures the original nature of man as eternal restlessness, curiosity and constructiveness. The child loves to take things apart and to "make things." Moreover, we, all of us, have enough of the self-regarding instinct for a social utilization of these tendencies; that is, we like to do things which we feel are useful and for which we are given credit. If such primary instincts are forever thwarted, the social misfit develops. If he finds his environment impossible to manipulate through lack of training, he will seek forgetfulness in some form of self-gratification. And some form is usually found in the unwholesome environment of the ordinary city street. If he comes in contact with those using narcotic drugs, they will find him responsive to imitation-suggestion.

Within the past ten years the vocational guidance movement has been developing to meet such educational and economic situations as we have outlined. The aim of this movement is to get hold of the child while he is still in school, to study his mental make-up, to arouse in him ambition, and then to give him guidance into a vocation for which he seems fitted. It has grappled with the problem of the child who asks for his working papers as soon as he is old enough, who often has no reason except that he is "tired of school." Studies made of these children in a number of cities show that without guidance they almost invariably drift into the blind alleys of the commercial and industrial world, from which they could be saved by a longer school life with specific trade or commercial training. The cities of Cincinnati, Chicago, Boston, Philadelphia and New York have more or less well-developed systems of guidance to lessen the number of misfits, and are working to increase their usefulness by devising better vocational, trade and commercial tests as well as by placement and careful follow-up work. This whole movement is based on the belief that happiness is a by-product of normal, useful activity, and that the child can be directed along the way, whether he be brilliant, mediocre or stupid. Its social philosophy teaches that the goal of society is to provide so flexible a social system that there shall be no misfits among the normal members of a population as a result of lack of guidance and training in the years when vocational choices are made.

If a proper scheme of vocational guidance can be put into operation, we shall have a better satisfied and happier industrial population, with fewer misfits from this social stratum to become gangsters and narcotic addicts. And since the heroin user is young, it is not too late to reclaim him to normal and happy living by vocational guidance and training in an institution which will teach him to face a new and

useful life after he is cured of his habit. The therapeutic value of vocational training has been evidenced with the cases of shell shock among the soldiers who are being reclaimed to happiness and usefulness under the direction of the federal Bureau for Vocational Education; and doubtless the same results can be obtained in the reclamation of youths who have lost their touch with reality in a less noble cause.

It is already understood that much of the success of vocational guidance depends on the follow-up, even with normal children, to counteract the restlessness of youth which impels them to move on at the first difficulty. Statistics show an average of three jobs for working children in the first two years. To counteract this tendency with the cured addicts, it will be imperative to devise a wise probation system. Many an otherwise hopeless misfit can be permanently saved by the supervision of a wise and experienced probation officer, acting with authority.

Under a proper system of classification in the institution for the after-care of the addict, it will be necessary to segregate the correctional, the mental defective, and the social misfit groups. We already have state provision for the care of correctional cases and mental defectives. The facilities may have to be increased, but the plan for care and training is already known through the work of such institutions as Letchworth Village for defectives and Elmira for correctional cases. But the problem of the misfit and of the drug user who appears normal except for the drug weakness has yet to be solved. That a solution is worth while is shown by the economic loss to the community resulting from their productive failure, their irregularity at work, and the tendency through their example toward an increase in the number of addicts.

When addicts of these types (social misfits and otherwise normal persons) are sent to an institution where they are to be restored to normality by both mental and physical therapy, the misfit can be aided by vocational guidance, as we have shown. By a study of the addict which will include intelligence and vocational tests, there is no reason why his aptitudes may not be recognized and developed as well as in the cases of the wounded soldier who finds it necessary to change his life work. And the very interest aroused by this new occupation, together with the absorption necessary in learning a new process, will lead the addict to forget the past. When the new vocation is entered, a judicious follow-up system should be maintained lest in moments of discouragement old memories reawaken and urge a return to the old haunts and habits.

ADDICTS OTHERWISE NORMAL

As to those persons otherwise normal who have become drug addicts, here we have a complicated problem. We may be dealing with a man or woman who has been doing work for which he is well trained and fitted. We may have such a person working under too great strain. Then the "last straw" is laid on the burden, and in the altogether human search for relief, even for a few hours, the drug is perhaps taken occasionally, and the habit finally formed. The literary genius who has to finish his manuscript for the publisher; the social worker whose district must be covered at whatever cost to herself; the physician or nurse with an epidemic sweeping the city, and who must not stop—any of these may realize too late that he has become a slave to the drug. What shall we do with him?

The newer psychology has distinguished the conscious activities of the human mind from its subconscious activities—those that take place on another level, and which include lost memories, impressions from the earliest period of infancy, and the effects of shock which have expanded beneath the level of the daily activities and which have spread from one association center to another until all the activities of life are influenced by the background of experiences that can be recalled with the greatest difficulty, if at all. This subconscious life, sometimes of great intensity, has a tremendous pull on the conscious daily life. We like people because of their resemblance to others whom we have forgotten. In the domain of smell are registered impres-

sions a thousand times as intense as those of taste. We have here a causation of likes, dislikes, attractions and repulsions whose origin we cannot understand. And buried in this part of the mind's activities is often the answer to the question why an otherwise normal person, physically well developed, makes decisions which we call regressions. Such regressive tendencies, if yielded to, mean disaster to the very soul.

Psychoanalysis as a form of mental therapy undertakes the reclamation of this unexplored part of the ego. And here is the greatest hope for the salvation of the otherwise normal person whose will is not strong enough to shake off the drug habit.

If, under psychoanalysis, the "sore spot" in the individual subconscious mind is discovered and a process of reeducation begun, the theory holds that there will be released an increased energy. And the reclamation of this "normal" addict will depend on the power he will have, under guidance, to direct this libido into higher thought and emotional levels. Studies made of individuals much given to day dreaming indicate that these dreamers have an oversensitive ego which makes their outer adjustments difficult, and thus makes for regression. The power to generalize their experiences is of the greatest assistance to these persons. And the pain of the world can be expressed in music; the longing of the world in marble, in painting, and in other creative forms. It is well recognized that man is a constructive animal, and is willing to spend himself in work in which he has joy and which brings him the respect of his fellow men. Teach this otherwise normal drug addict to irradiate and sublimate this libido which he is so wantonly wasting on the fetish of drug addiction. His strong desire is a measure of his energy. Let him be taught to direct that energy into wholesome channels which will give him as great pleasure and which will recreate his soul.

Such is the task of the men and women in charge of the institution for the educated men and women who are drug addicts: They are to be both trained and sympathetic, wholesome and strong-willed; friends and guides into a new life in which the base desires for self-gratification is, not suppressed, but directed into new channels which will make for the happiness of the individual and the race.

RECOMMENDATIONS

We therefore recommend:

1. That the ambulatory treatment of drug addiction, as far as it relates to prescribing and dispensing of narcotic drugs to addicts for self-administration at their convenience, be emphatically condemned.

2. That heroin be eliminated from all medicinal preparations, and that it should not be administered, prescribed or dispensed; and that the importation, manufacture and sale of heroin should be prohibited in the United States.

3. That the bills introduced by Senator France, No. 2785, and Representative Rainey, No. 11778, to provide aid from the United States for the several states in prevention and control of drug addiction and the care and treatment of drug addicts be approved, and that Senator France and Representative Rainey be so notified.

4. In view of the statement in a government report that about 90 per cent. of the amount of narcotic drugs entered for consumption is used for other than medical purposes, the Treasury Department is respectfully urged to continue to study and report on the narcotic drug situation, including the question of government control of these drugs.

5. That the Bureau of Public Health Service of the Treasury Department be respectfully requested to continue the compilation of state laws and regulations relating to habit-forming drugs and bring them up to date.

THE SCIENTIFIC ASSEMBLY

THE OPENING GENERAL MEETING

Tuesday Evening, April 27

The opening meeting of the Association was held at the Shriners' Temple, and was called to order at 8:30 p. m. by the President, Dr. Alexander Lambert, New York.

Prayer was offered by Bishop J. M. Laval.

Dr. Albert E. Fossier, Chairman of the Local Committee of Arrangements, announced the various entertainments to be given the members of the Association and its guests, and stated that the committee had earnestly cooperated with the officers of the Association to make the New Orleans session a success, both from a social and a scientific standpoint.

Addresses of Welcome

In the absence of Hon. Martin Behrman, mayor of New Orleans, Mr. A. G. Ricks welcomed the members and guests to New Orleans on behalf of the mayor.

ADDRESS OF WELCOME BY DR. HOMER DUPUY, PRESIDENT OF THE LOUISIANA STATE MEDICAL SOCIETY

Dr. Dupuy said in part: On me is bestowed the distinguished privilege and great honor of bringing to this Association a message of cordial welcome from our great state society. We knew that when you accepted the invitation to meet in New Orleans, we had a task of some magnitude; but with a united profession, with considerate action, unified sentiment and irrepressible enthusiasm, we buckled down to the task, and it is now up to you to witness the results of our work.

New Orleans loves you; Louisiana loves you and honors you, and hopes that when you leave us, you will carry away with you happy and pleasant recollections of your visit to this city. We extend to you a hearty welcome to New Orleans.

ADDRESS OF WELCOME BY HON. JOHN M. PARKER, GOVERNOR-ELECT OF LOUISIANA

Mr. Parker said in part:

Mr. President and Members of the American Medical Association: Today, probably for the first time in the history of Louisiana, we have made arrangements by which we see our way clear to take proper care of our insane asylums, our feeble-minded asylums, and the other institutions that stand close and dear to the heart of every sincere medical man.

Within the last few years in traveling over the state of Louisiana, I have been impressed with the fact that we do not give proper heed and devote proper care to those unfortunates that are left on our hands. We have overlooked too often the fact that those who are absolutely unable to help themselves and who have been dependent on the charity of state and cities represent a steadily growing number of people to whom you minister, and to whom your services as guardian angels are more needed than any other class of people in the world. I have made up my mind regarding one thing, and that is, while I am governor, no politics shall directly or indirectly creep into any of our institutions. (Applause.)

I am delighted to have the privilege of appearing before you. I want your help in this work. Our institutions should be regarded as sacred, and their interests upheld and zealously fought for by the members of your profession.

I trust that when you return to New Orleans in the next few years, it will be a source of great pleasure and pride for us to tell you what has been accomplished by having taken advantage of your valuable assistance and influence in connection with our institutions. (Applause.)

ADDRESS OF THE PRESIDENT

Admiral William C. Braisted was introduced as President of the Association, and delivered his address, entitled, "The Obligations of Medicine in Relation to General Education," which was published in THE JOURNAL, May 1, 1920, p. 1203.

TETANY

The increased irritability of the nervous system associated with muscular tremors and occasionally convulsive seizures, a group of symptoms designated as tetany, not long ago appeared likely to find a scientific explanation in the study of the functions of the parathyroid glands. Excision of all of the latter leads to the characteristic nervous manifestations of tetany. These are also noted in man in association with gastric disease, particularly in patients who have long suffered from obstruction at the pyloric orifice. The attempt to relate gastric tetany to parathyroid insufficiency has encountered obstacles; for the parathyroid structures usually have been found to appear intact in these cases, and the condition is often relieved by gastro-enterostomy. It will therefore be understood why medication with parathyroid substance has been of questionable advantage in the treatment of gastric tetany. The results have been disappointing thus far, if they may not actually be described as failures.

Even if the cases of tetany, as they are seen during pregnancy and after parturition, in infants, in gastric disease, in certain occupations, and in parathyroid insufficiency have no apparent immediate etiologic relationship, it is not impossible that in ultimate analysis the increased nervous irritability may have a common metabolic cause. Wilson¹ and his co-workers at the Johns Hopkins Medical School found that, following parathyroidectomy in dogs, the equilibrium between acids and bases is displaced in favor of the bases, and that in tetany which develops after such a procedure there is well marked alkalosis. The results have been confirmed by McCann² at the Harvard Medical School, who agrees that there is a marked increase in the carbon dioxid-combining power of the blood plasma, coincident with the development of tetany.

McCann has extended the study to the phenomena of gastric tetany. He found that after operations on the stomach which exclude the acid secreted from the duodenum, tetany develops, accompanied by an increase

in the carbon dioxid-combining power of the plasma similar to that of parathyroid tetany. These facts have led McCann, like some of his predecessors, to the conclusion that tetany is a condition of alkalosis in which a disproportion between rates of secretion of acids and alkalis by the gastro-intestinal tract may be a factor.

A disproportion of acids and bases leading to accumulation of the latter—an alkalosis—might conceivably be due to a heaping up of alkali in the organism or to a withdrawal of acid such as the gastric juice represents. Tetanic symptoms can, indeed, be induced by excessive injections of sodium carbonate or bicarbonate. MacCallum³ and his collaborators have presented a somewhat different feature for consideration. They noted that when the pylorus is obstructed and the gastric juice with its hydrochloric acid is constantly removed, there ensues a decrease in the chlorin of the blood plasma and a consequent increase in the alkali reserve which becomes extreme. The electrical excitability of the nerves is heightened, and spontaneous twitchings arise. These are symptoms of gastric tetany. According to MacCallum, all this can be prevented by constantly furnishing a large supply of chlorids. He states that it is less easy to cure the condition by the administration of chlorids. It is easy to understand that sodium chlorid, which is reported to be efficacious in this experimental gastric tetany, might serve as a source of hydrochloric acid. But what becomes of the sodium ion? And why are chlorids more efficacious, as we are told, than acids? Here are seemingly conflicting factors which need to be reconciled or explained before a rational treatment of gastric tetany can finally be instituted.

RACIAL MORTALITY

The United States offers an opportunity for studying the mortality of various race stocks such as has probably never been presented before in the world's history. Diverse races of mankind are here gathered together under identical climatic and similar social and economic conditions. In the case of certain races, the absolute numbers are large enough to warrant definite conclusions. Several more or less elaborate studies of racial mortality in some of the Eastern states and cities have appeared since the census of 1890, and one of the most important of these has recently been published by Dublin and Baker.⁴

This investigation deals with the 1910 mortality of race stocks in the states of Pennsylvania and New York. Six nationalities, as distinguished by the country of birth, were present in numbers sufficient to justify differentiation: Austro-Hungarians, Russians, Italians, Germans, British and Irish. In Pennsylvania in 1910 these six foreign groups together comprised

3. MacCallum, W. G.; Lintz, Joseph; Vermilze, H. N.; Leggett, T. H., and Boas, E.: The Effect of Pyloric Obstruction in Relation to Gastric Tetany, *Bull. Johns Hopkins Hosp.* **31**: 1 (Jan.) 1920.

4. Dublin and Baker: *Quart. Pub. Am. Statist. Assn.* **17**: 13, 1920.

18.0 per cent. of the total white population and 93.3 per cent. of all the foreign born; in New York 26.4 of the total white population and 86.9 per cent. of all the foreign born.

In correspondence with previous statistical investigations, it is shown that the group composed of the native born of native parents has a much lower mortality than the native born of foreign or mixed parentage and than the foreign born. This is true for both sexes and for virtually every age period; but the disparity is greatest at the adult ages. The foreign born and the native born of foreign or mixed parentage have mortality rates agreeing much more closely with one another than with the native stock.

Three of the foreign born groups (Austro-Hungarian, Russian and Italian) present mortality conditions which, when compared with those for the native born, are fairly favorable, except for those age groups exposed by industrial conditions to special occupational risks. Italians, for example, in Pennsylvania and New York State show, on the whole, little difference in their death rates from those prevailing in their home country.

Quite different is the position of the foreign born German, British and Irish living in the United States. In these groups the mortality is very high compared with the mortality in native born Americans of native parentage; for each racial group, moreover, the death rates in the United States are less favorable than in their native land, even apart from their greater liability to death from violence in hazardous employments.

Analysis of the rates from individual causes of death reveals some facts of great significance. As in previous inquiries of this sort, the outstanding feature with regard to pulmonary tuberculosis is the great handicap of the Irish. In both New York and Pennsylvania the rate for this cause among Irish males, ages 25-44, is twice as large as for natives; Pennsylvania, 376:185; New York, 663:352. The Irish also show high death rates from pneumonia, cancer, organic diseases of the heart and Bright's disease, although in their own country such excessive rates do not occur. At ages 65-84 Irish males at home show a mortality from Bright's disease of but 115 per hundred thousand as against the very high rates of 1,146 and 1,299 for Irish born males living in Pennsylvania and New York. The foreign born groups of German and British stock show a similar, although less striking, excess from pulmonary tuberculosis and from the so-called degenerative diseases. It is certainly noteworthy that while the rate for nephritis and Bright's disease in British males, ages 45-64, living in England and Wales was 116 per hundred thousand, the figures for Bright's disease alone among British born males living in Pennsylvania and New York were 240 and 288, respectively.

Dublin and Baker raise the point whether the common assumption that immigrants to this country rep-

resent the most vigorous strains among their own people is really justified. The results of this and other studies on racial mortality do not permit an unqualified affirmation. Those who maintain that centuries of economic and social struggle in the older countries have brought to the top the best racial material, leaving at the bottom the physically weak and consequently economically unsuccessful who seek to better themselves by emigration, may find some support in such mortality records as here cited. At all events, the importance of similar studies based on the results of the 1920 census is decidedly manifest.

FACTORS IN THE PRODUCTION OF EDEMA

The problems of the etiology of the various types of edema are far from being solved. The significance of a renal factor interfering with normal excretion has long been appreciated; but there are without doubt, numerous extrarenal factors that may play an important part. Thus, alterations in the vascular permeability, preventing the customary passage of fluids from the blood vessels, may affect the circulation so as to damage the kidney functions. Experimental edema can be produced by the administration of certain poisons, such as arsenic or snake venom. Whether they act solely on the renal vessels or on capillaries elsewhere in the body is not always clear; at any rate, they injure the vessels sufficiently to prevent the usual distribution or excretion of fluids, and edema results. Again, as illustrations of extrarenal factors in edema, it has been suggested that changes may occur in the physical or chemical character of the tissues so that they retain water in excess of their usual quota.¹

Epstein² has described cases of edema associated with parenchymatous nephritis in which a hydremia occurs accompanied by a diminished amount of protein in the blood.³ The latter is assumed to be due to loss of protein through the urine. Epstein advises the liberal feeding of protein as the most effective way of managing such cases. We have already referred to preliminary reports on the unexpected appearance of edema in animals that were kept on a diet largely made up of carrots.⁴ Even in the earlier stages of Kohman's investigation it appeared likely that the malnutrition responsible for the edema was not due to lack of fat, to which "war dropsy" has frequently been ascribed, but rather to an insufficiency of protein in the diet.

The further prosecution of these important studies has served to fasten responsibility for the edema in

1. These various factors are discussed by Hewlett, A. W.: *Pathological Physiology of Internal Diseases*, New York, 1917, p. 437.

2. Epstein, A. A.: Concerning the Causation of Edema in Chronic Parenchymatous Nephritis, *Am. J. M. Sc.* **154**: 638 (Nov.) 1917.

3. The theory is discussed in The Cause of Edema, Correspondence, *J. A. M. A.* **73**: 782 (Sept. 6) 1919.

4. Denton, M. C. and Kohman, E.: Feeding Experiments with Raw and Boiled Carrots, *J. Biol. Chem.* **36**: 249 (Nov.) 1918. Kohman, E. A.: A Preliminary Note on the Experimental Production of Edema as Related to "War Dropsy," *Proc. Soc. Exper. Biol. & Med.* **16**: 121 (April 16) 1919. The Cause of War Edema, editorial, *J. A. M. A.* **73**: 274 (July 26) 1919.

Kohman's experiments even more convincingly on the protein factor.⁵ When young rats are fed diets in which carrots are the only source of protein, a large percentage of the animals develop edema. This is not due to a lack of fat or vitamins, as experiments specially planned to include an abundance of these have demonstrated. Salts do not play any appreciable part in the production of this type of edema, for even when the salt content is doubled there is no noticeable effect on the occurrence of edema. The latter is not due to simple starvation

on low calory intake, for the mere replacement of part of the carbohydrate with an adequate protein, casein, serves to avert edema on an otherwise unaltered diet. Henceforth, therefore, the level of protein intake must not be overlooked when symptoms of edema develop; and the possibility of protein feeding must be considered as a therapeutic measure. This is not intended to signify that the suggestions just offered have universal application. Kahn⁶ has estimated the protein content of the blood in a number of cases of parenchymatous nephritis with edema of varying grades without finding deviations of the sort described by Epstein and which, according to the latter, should be benefited by a high protein diet. Kahn regards the cases of so-called nephrosis described by Epstein as very rare. Reminding us of the remarkable stability of the blood serum protein level even in disease and of the difficulty in altering it appreciably by feeding protein, Kahn concludes that "feeding patients suffering with chronic parenchymatous nephritis on a protein-rich, fat-poor diet is a rather risky undertaking." In view of the striking experimental evidence of interrelations between protein deficiency and edema, however, clinical investigators should not abandon the suggestions emanating from the physiologic laboratory without more conclusive assurances that they cannot apply to human disease.

Current Comment

THE PRESIDENT-ELECT, DR. HUBERT WORK

Since 1916, the House of Delegates of the American Medical Association has been a peculiarly efficient representative body. Delegates representing the organized medical profession of the United States have met, have expressed their individual views, have passed resolutions and taken action on questions of great moment to

our profession and to the nation, have participated in lively debate, and in a kindly, democratic manner, without friction or ill feeling. To no one is this state of affairs due so much as to Dr. Hubert Work of Colorado, first Speaker of the House of Delegates, and now President-Elect of the American Medical Association. Dr. Work was born near Marion, Pa., July 3, 1860. By a happy coincidence, the date of his birth approximates the most patriotic date in our history; his name indicates the chief function in his career. He was graduated from the University of Pennsylvania School of Medicine in 1885. Early in his professional career he was engaged in public medical service; during the late eighties he was a member of the State Board of Medical Examiners of Colorado; for four years he was president of the State Board of Health and later president of the Colorado State Medical Society. In 1904 he began his first

HUBERT WORK, M.D.
PRESIDENT-ELECT OF THE AMERICAN MEDICAL ASSOCIATION

term as a member of the House of Delegates, and since that date he has served the American Medical Association continuously as a member of the House, as a member of the Judicial Council, and finally as Speaker of the House. Only those acquainted with the intricacies of parliamentary procedure can realize how well fitted Dr. Work has been for his task: always calm, reserved, and ever ready with kind comment or witty repartee, his spirit has infused into the body of delegates the desire for progress and cooperation, which has resulted in efficient action. With all his service to medicine and to the American Medical Association, he has yet given himself largely to other organizations. As a citizen he has achieved the distinction of candidacy

5. Kohman, E. A.: The Experimental Production of Edema as Related to Protein Deficiency, *Am. J. Physiol.* 51: 185 (Feb.) 1920.

6. Kahn, Max: The Protein and Lipin Content of Blood Serum in the Nephritides, *Arch. Int. Med.* 25: 112 (Jan.) 1920.

for the United States Senate and was defeated by a small majority. For several years he has represented his state as a member of the Republican National Committee, a position of no small importance in our political system. During the war, Colonel Work was medical adviser of the Provost Marshal General, and here his diplomatic qualities were of inestimable service in correlating the work of the medical department of the army with that of the Provost Marshal General's Office. In electing him to the highest position it has to bestow, the American Medical Association shows its appreciation of the worth of his services to the medical profession and to the public.

THE ANNUAL SESSION

Prior to the meeting there was considerable anxiety on the part of many concerning the success of the New Orleans Session of the American Medical Association, the anxiety being due to the supposition that there was not a sufficient number of hotels to accommodate the expected attendance. From various quarters came reports that men were not planning to attend because of this lack of hotel accommodations, and, naturally, those pessimistically inclined looked for a moderately small registration. As a matter of fact, the attendance at New Orleans exceeded the expectations of the most optimistic; the registration reached 3,681. Hence, so far as number is concerned, the Session was an immense success. But it was successful from every point of view—in the unusual social features provided by the hospitable physicians and citizens of the convention city; in the attention given to the exhibits, and in the scientific character of the work of the sections. The social features were typical of the city. The largest available hall was taxed to such an extent by the Carnival Ball, which took the place of the usual President's Reception and Ball, that many of those attending the session were unable to gain admission. The grand Fête Champêtre and Pageant at the City Park was a beautiful spectacle—it was such as could be presented in but few other cities. The House of Delegates, in an unusually important session, took timely action on questions of great interest to both the medical profession and the public, the details of which will be found in the published minutes. Among other things, an exhaustive report on the use and abuse of narcotic drugs was submitted; action was taken urging Congress to make necessary appropriations for the publication of the Medical History of the World War; and resolutions were adopted declaring opposition to the institution of any plan embodying the system of compulsory health insurance. The Local Committee on Arrangements and the medical profession of New Orleans and Louisiana well deserved the thanks conferred on them by the House of Delegates. Their untiring efforts made the New Orleans Session the success it was. In spite of the fact that the attendance was so large as to tax the hotel accommodations of the city to the limit, the Session will be remembered with pleasure by all who attended. The arranging for the annual session of the Association, including the provision of

numerous meeting places, large exhibit space and lodgings for from four thousand to five thousand physicians and their guests, is no small task. The cooperation of the Local Committee on Arrangements is the determining factor in the success of the Session. The New Orleans Committee, which had unique and difficult problems to handle, did its work well.

CONGENITAL ECTODERMAL DEFECTS

Congenital ectodermal defects, such as aplasia of the teeth or absence of circumscribed patches of skin, are by no means unknown to medical observers. The combined absence of teeth and hair is rarer. Perhaps the most unusual anomaly of the ectodermal tissues is found in persons exhibiting a congenital absence of teeth, total alopecia, and also a lack of both sweat and sebaceous glands in the skin. A case of this sort, the second of its kind reported in the American journals, and the sixth in the world's literature of the subject, has been studied at the Mayo Clinic by Goeckermann.¹ The patients of this type have usually presented features that suggest the existence of heredosyphilis. If this were responsible for the cutaneous defects, one would expect to find signs of atrophic changes in the skin. Microscopic examinations of sections from the epidermal structures in the Rochester patient, however, showed a total absence of sudoriferous and pilosebaceous structures. There were no signs of regressive changes in the skin. There was an entire absence of such cell inclusions as might warrant an assumption that embryonal vestiges of lanugo hair and sweat glands had ever existed. Hence the influence of syphilis in the production of these congenital defects is probably nil. If it is present, this is probably only an incidental feature. Perhaps these congenital defects of the ectoderm are not as rare as medical history suggests. Frequently the persons involved are in excellent health and have no occasion to submit to such critical examinations as might reveal subtle defects of the skin. Only a few years ago the Stokes-Adams syndrome was an apparently rare condition. When attention was drawn to its precise identification, cases of heart block began to multiply in surprising numbers. Perhaps congenital ectodermal defects of the sort described by Goeckermann and exhibiting a total absence of sweat glands, an almost total absence of sebaceous glands, a hypotrichosis with absence of lanugo hair, and a dental aplasia, will be discovered to be less rare when it is appreciated that the features which they present actually exist.

1. Goeckermann, W. H.: Congenital Ectodermal Defect, with Report of a Case, *Arch. Dermat. & Syph.* 38: 396 (April) 1920.

Significance of Pain.—To understand the full significance of pain in any case, we have to know a great many matters which are still hidden from us. The tissues capable of producing pain, the nerves in whose distribution the pain is felt, the manner in which the pain spreads, and the laws governing the spread of pain; the character of the pain itself; the manner of its onset and its variations, and the phenomena with which it is associated, are all matters which it is necessary to understand before we are qualified to undertake an investigation into disease.—J. MacKenzie *Brit M. J.* 1:109 (Jan. 24) 1920.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Health Law Valid.—By the decision of Judge Leon McCord, in the Montgomery Circuit Court, the State Board of Health of Alabama was declared to have been created by a valid law, and will continue to exercise the duties of the administration of the state health law. An appeal has been taken by physicians of Birmingham who allege that in violation of the provisions of the constitution, the legislature provided that the board of health should be named by the Alabama Medical Association, a private corporation.

State Association Meeting.—At the fifty-third annual meeting of the Medical Association of Alabama held in Anniston, April 20-22, under the presidency of Dr. James S. McLester, Montgomery, Montgomery was selected as the place of meeting for 1921, and the following officers were elected: president, Dr. Louis W. Johnston, Tuskegee; vice presidents, Drs. Thomas J. Brothers, Anniston, and John C. McLeod, Opp; censors, Drs. William R. Jackson and Vivian P. Gaines, Mobile, and Walter S. Britt, Eufala. Dr. Henry A. Christian of Harvard University delivered the Jerome Cochran Lecture, on "Bright's Disease with Special Reference to Its Treatment."

CALIFORNIA

Higher Entrance Requirements in University of California Medical School.—It is stated, officially, that in and after August, 1922, students matriculating in the University of California Medical School will be required to have completed satisfactorily not less than three years of collegiate work. This raises the minimum collegiate requirement from two to three years.

ILLINOIS

Central Illinois Physicians to Meet.—The Central Illinois Medical Society will be the guests of the Decatur Medical Society, May 25. The principal address will be delivered by Dr. Charles Spencer Williamson, Chicago.

Personal.—Dr. J. Warren Van Derslice, Oak Park, has been elected president of the Colonial Club, Oak Park.—Dr. Howard B. Boone, Chandlerlerville, has been reappointed local surgeon for the Chicago, Peoria and St. Louis railroad.

Clinic for Rock Island County.—The Rock Island County Board of Supervisors has voted \$6,000 for the establishment of a venereal disease clinic in the county. The state will appropriate \$200 a month toward the upkeep of the clinic.

Medical Veterans to Meet.—A meeting of the Medical Veterans of the World War will be held at the Christian Union Church, Rockford, May 19, to organize the Illinois section of the association. Luncheon will be served. Any physician who was in the service during the World War or who was a member of a local or district draft board or advisory board is eligible for membership. Notification should be sent to Dr. John E. Tuite, Rockford.

Chicago

Short Term Nurses Graduate.—The graduating exercises of the third class of the training school for home and public health nursing, established by Dr. John Dill Robertson, health commissioner of Chicago, were held April 27, when a class of 609 was graduated. The work of the new course began May 3.

Medical Society Banquet.—The annual banquet of the Aux Plaines branch of the Chicago Medical Society was held at Oak Park, April 15, with an attendance of more than 300. The principal speakers were Mr. Marquis Eaton, chairman of the Chicago chapter of the American Red Cross, Dr. J. Warren Van Derslice, Oak Park, president of the Illinois State Medical Society and Dr. Norman Bridge of Los Angeles.

IOWA

Middleton Returns.—Dr. Edward D. Middleton has returned to Davenport after prolonged service during the World War, in which he served with the Canadian Expe-

ditionary Forces, and was stationed on the French and Belgian fronts, at the Dardanelles, and in Palestine, Egypt, Bulgaria and Southern Russia.

State Society Meeting.—The sixty-ninth annual meeting of the Iowa State Medical Society will be held at Des Moines, May 12 to 14, under the presidency of Dr. William L. Allen, Davenport. Drs. Robert H. Babcock, Chicago, and Charles H. Mayo, Rochester, Minn., will deliver the addresses in medicine and surgery, respectively.

Reversed by Supreme Court.—The Iowa Supreme Court reversed a verdict of the Dubuque District Court which found Dr. C. Allen Snyder, Dubuque, guilty of second degree murder. Dr. Snyder is said to have been charged with performing an illegal operation on Mrs. Grace Wolfe, from which she died in 1917. In reversing the verdict the supreme court held that the evidence was insufficient to warrant conviction.

MARYLAND

Bequest to Johns Hopkins.—Through the first administration account of the estate of Eugene G. Mergenthaler, the Johns Hopkins University has received securities and cash amounting to \$186,444.22 of the legacy of \$200,000 bequeathed the university to build a laboratory, a building devoted to the technical arts or a library building.

Personal.—Sir Gregory Foster, Lieut.-Col. Thomas Renton Elliott, Dr. George F. Blacker and Dr. Grafton Elliot Smith, British physicians, left for Philadelphia after two days in Baltimore inspecting the Johns Hopkins Medical School. The physicians came at the invitation of the Rockefeller Foundation and their itinerary permits inspection of hospitals in Philadelphia, New York, Boston, Chicago and St. Louis.—Dr. Harry M. Slade, Reisterstown, has been reappointed secretary to the board of health of Baltimore County and health officer of the fourth district for two years. The other district health officers appointed for the same period are: Drs. Charles L. Mattfeldt, Catonsville; Harry F. Shipley, Granite; Henry A. Naylor, Pikesville; James H. Wilson, Fowlesburg; Eugene W. Heyde, Parkton; Alexander R. Mitchell, Hereford; John H. Drach, Cockeysville; Walter S. Carswell, Ruxton; Robert W. Shermantine, Sparks; James F. H. Gorsuch, Fork; Walter M. Carmine, Sparrows Point; Thomas B. Hall, Mt. Winans; Harry W. Wheaton, Baltimore, and John W. Harrison, Middle River.—Dr. William H. Welch and Dr. Ira Remsen, both of Johns Hopkins University, have been appointed to the Board of Electors for the Hall of Fame of New York University.—Dr. Cyril H. Haas, who was in Turkey several years before the war and who served at the Turkish capital during the war, recently delivered several lectures in the medical amphitheater of the Johns Hopkins Hospital. He came to the United States to speak at the recent conference of student volunteers at Des Moines, Iowa.—Dr. Warren H. Lewis, professor of physiologic anatomy at the Johns Hopkins Medical School, has been elected an honorary member of the Society of Medicine, Ghent. Dr. John J. Abel, Woodlawn, professor of pharmacology at Johns Hopkins University; Dr. William S. Halsted, director of the surgical clinic at the Johns Hopkins Hospital, and Dr. Elmer V. McCollum of the Johns Hopkins School of Hygiene and Public Health have been made associate members of the Royal Society of Medical and Natural Sciences of Brussels.

MISSISSIPPI

Appropriation for Feeble-minded School.—The state legislature passed a bill just before adjournment, carrying an appropriation of \$100,000 to establish a state school for the feeble-minded.

Hospital for Meridian.—The Meridian board of trade has presented the Matty Hersee Charity Hospital buildings, land and equipment to the city of Meridian. The board recently acquired the property by raising a public subscription fund from the city and have deeded the institution to the city free from all debt or other incumbrances.

New Building for Medical School.—The Mississippi legislature has appropriated \$250,000 for a new chemical building at the University of Mississippi which will provide laboratory and other facilities for students in the medical school. An additional appropriation of \$10,000 was made to secure permanent equipment for the medical school, exclusive of chemistry. Additional funds were appropriated for the university with which salaries of all teachers could be reasonably increased. The total appropriation for the university exceeds \$1,000,000.

MISSOURI

Polyclinic at St. Joseph.—A polyclinic is to be established at Community Hall, St. Joseph, under the charge of Dr. George R. Stevenson. Seven rooms have been set aside for the use of the clinic.

Damages Awarded Physician.—In the trial of the suit in the Barry County Circuit Court of Dr. William T. J. Bailey, Cassville, against J. W. LeCompte, Cassville, for damages received when he was attacked by a bulldog at the LeCompte home, the jury awarded \$1,000 to the physician.

Library Club Election.—At the annual meeting of the Kansas City Library Club, April 12, Drs. Edward H. Skinner, Matthew W. Pickard and Logan Clendening were elected directors for three years. At the meeting of the directors, April 16, Dr. Edward H. Skinner was elected president, Dr. Matthew W. Pickard, vice president, and Dr. Harold P. Kuhn, secretary-treasurer.

Health Officers Organize.—In response to a call issued by the state board of health a meeting of deputy state commissioners of health was held at Jefferson City, April 6, and a permanent organization was formed under the name of the Missouri Health Officers' Association. The following officers were elected: president, Dr. G. C. Rogers, Clinton; vice presidents, Drs. Ulysses F. Kerr, Springfield, and Tolman W. Cotton, Van Buren; secretary, Dr. George H. Jones, Jefferson City, and directors, Drs. James W. Bruton, Ozark, Robert E. Crabtree, Butler, and William P. Smith, Troy.

NEBRASKA

Roentgenologists Elect Officers.—At the annual meeting of the Omaha Roentgen Society, March 27, Dr. Joseph Colt Bloodgood of Johns Hopkins University delivered the principal address. Dr. B. H. Harms was elected president; Dr. Norman C. Prince, vice president, and Dr. William L. Ross, secretary.

Personal.—Dr. W. H. Clatterly has been appointed city physician of Lincoln, succeeding Dr. Herman A. Gerbig.—Phelps County Medical Association gave a dinner in Holdrege, April 16, in honor of the seventy-fifth birthday of Dr. Samuel F. Sanders. Dr. Rachael A. W. Long was chairman of the committee of arrangements.

NEW YORK

Albany Medical College Recognized.—A letter from the superintendent of public instruction of Pennsylvania states that recognition was restored to the Albany Medical College by the Pennsylvania Bureau of Medical Education and Licensure, Oct. 15, 1919. This is a correction to Table D published in THE JOURNAL of April 17, which indicated that the Albany Medical College was not recognized in Pennsylvania.

Tuberculosis Clinic.—The Buffalo Tuberculosis Association has made appropriation for a free clinic for the diagnosis of tuberculosis to be opened in Tonawanda, May 6, under the charge of Drs. John H. Pryor, John G. Stowe and C. Grabau, all of Buffalo.—A free clinic is being held at Rome Court House under the auspices of the Oneida County Tuberculosis Committee, the state department of health, Rome Board of Health and Dr. Charles R. Mahady, the local health officer.

New York City

Dr. Wilmer Addresses Academy.—At the meeting of the New York Academy of Medicine, April 15, a paper was read by Dr. William Holland Wilmer, Washington, D. C., on the "Injurious Effects on the Eye of Various Toxemias."

Association of Tuberculosis Clinics.—The Association of Tuberculosis Clinics, which originated in 1906, now has a membership of thirty clinics, and 280 active and associate members. The objects of the association are the organization of dispensary control of tuberculosis in New York City; the development of a uniform system of operating dispensaries organized for this purpose; the placing of patients under observation until they are satisfactorily disposed of; the prevention of patients' drifting from one dispensary to another; the facilitation of the attendance of the patients at dispensaries most convenient to their home; the facilitation of the work of visiting nurses in the homes; the provision for each patient requiring it of assistance by a system of special funds or benevolent organizations, and proper hospital, dispensary or sanatorium care; the cooperation with, and assistance to as far as possible, the department of health in the supervision of tuberculosis. Dr. James Alexander Miller

has been reelected president of the association and the present board of directors consists of Dr. John S. Billings, Jr., representing the New York Tuberculosis Association; Miss Elizabeth Gregg, representing the nurses department of health; Dr. Dwight Clifford Martin, representing the department of health, Manhattan; Dr. Victor Miltenberg, representing the department of health, Queens; Dr. James A. Miller, representing Bellevue Hospital; Mr. Graves Moore, representing Brooklyn Bureau of Charities; Dr. Arthur E. Neergaard, representing the Presbyterian Hospital; Miss Blanche Potter, representing auxiliaries; Dr. Joseph C. Roper, representing the New York Hospital; Dr. Henry G. Schweitzer, representing the department of health, Bronx; Dr. Ambrose A. Scouler, representing the department of health, Brooklyn, and Dr. Max Taschman, representing Mt. Sinai Hospital.

NORTH CAROLINA

Health Officers Meet.—At the annual meeting of the North Carolina Health Association held in Charlotte, April 19, Dr. Romulus L. Carlton, Winston-Salem, was elected president; Dr. Lawrence J. Smith, Wilmington, vice president, and Dr. George M. Cooper, Raleigh, secretary and treasurer.

Personal.—Dr. John Whitehead, Salisbury, who has been seriously ill at his home, is much improved.—Dr. Carl A. Nevs, Greeneville, S. C., has been appointed acting chief narcotic agent for North Carolina.—Dr. Richard F. Yarbrough, Louisburg, has resigned as physician at the State College, Raleigh.

Hospital Men Elect Officers.—The North Carolina Hospital Association held its annual meeting in Charlotte, April 19, and elected the following officers: president, Dr. James M. Parrott, Kingston; vice presidents, Drs. James R. Alexander, Charlotte; Paul R. MacFadyen, Concord, and Miss Gilbert Muse, High Point; and secretary-treasurer, Dr. John Q. Myers, Charlotte.

State Board of Examiners Selected.—At the meeting of the Medical Society of the State of North Carolina the following were nominated members of the state board of medical examiners: Drs. Lester A. Crowell, Lincolnton; Lucius N. Glenn, Gastonia; John G. Murphy, Wilmington; Clarence A. Shore, Raleigh; William M. Jones, Greensboro; William P. Holt, Duke, and Kemp P. B. Bonner, Morehead City.

Society Meeting.—The sixty-seventh annual meeting of the Medical Society of the State of North Carolina was held in Charlotte, April 20 to 22, under the presidency of Dr. Carl V. Reynolds, Asheville. The following officers were elected: president, Dr. Thomas E. Anderson, Statesville; vice presidents, Drs. Charles S. Lawrence, Winston-Salem, William H. Ward, Plymouth, and John M. Manning, Durham; secretary-treasurer, Dr. Benjamin K. Hays, Oxford (reelected), and Dr. Lewis B. McBrayer, Sanatorium, was made active secretary-treasurer during the absence of Dr. Hays in Denver. Pinehurst was selected as the place of meeting for 1921.

OHIO

Conference of Health Commissioners.—The first session of the conference of Ohio health commissioners with the state department of health will be held in Columbus, May 12-14.

Tribute to Dr. Holmes.—The Carnegie Corporation of New York, has donated \$250,000 to the University of Cincinnati College of Medicine as a tribute to the late Dr. Christian R. Holmes.

Medical School to Be Reorganized.—It is reported that the Ohio-Miami Medical College of the University of Cincinnati will be reorganized, by which the heads of the departments of medicine, surgery and obstetrics will be on a full time basis, following the plan suggested by the General Education Board.

Maternity Hospitals Must Be Licensed.—All institutions, maternity or lying-in hospitals or institutions admitting maternity cases are now required to obtain a license from the state department of health. Heretofore only institutions engaged exclusively in this work have been licensed. The regulations provide that certain sanitary equipment and measures must be employed, and that records be kept for both mother and child.

Personal.—Dr. Charles Saur, Norwood, has been appointed physician to the Hamilton County Home, succeeding Dr. Charles A. Neal, Norwood, resigned.—Dr. Levi M. Jones, Jamestown, fell while going to make a professional call, fracturing his nose and sustaining severe bruises of the face.—Dr. Louis A. Thompson, for four years surgeon of the

Central Branch, National Military Home Hospital, has been appointed surgeon at the Hampton, Va., Soldiers' Home.—Dr. George W. Wood, Wilmington, has been appointed resident physician to the Ohio Soldiers' and Sailors' Home, Xenia.

PENNSYLVANIA

Hospital for Drug Addicts.—A site has been purchased by the state in Cumberland County on which to erect an institution for drug addicts. An appropriation of \$30,000 was provided by the legislature for establishment of the institution and it is planned to erect three cottages and to improve the buildings already on the site.

New Medical Organization.—Physicians of Beechview, West Liberty, Brookline, Dormont and Mt. Lebanon met in Dormont, April 22, and organized the South Hill Medical Association which will eventually become a branch of the Allegheny County Medical Society. Dr. Chauncey L. Palmer, Mt. Lebanon, was elected president, and Dr. John L. Steffy, Brookline, secretary.

Personal.—Dr. John F. Norris, for several years superintendent of the Somerset Home and Hospital, has resigned to accept a similar position in a hospital in the West.—Dr. James F. Trimble, Greensburg, has been appointed medical director of Westmoreland County.—Dr. Clare B. Kirk, Mill Hall, has been made chief of the tuberculosis dispensary at Lockhaven.—Dr. John B. Critchfield, Lockhaven, has been appointed state medical supervisor of the state department of health, succeeding Dr. John Herbert Waite, Flemington, resigned.

Commission to Advise on Legislation Relative to Insanity.—The last legislature of Pennsylvania created a commission to revise and codify the laws relating to the insane and feeble-minded. The commission appointed includes: Hon. Isaac Johnston, Media; Drs. Owen Copp and Charles Frazier, Philadelphia; Dr. Theodore Diller, Pittsburgh, and Daniel Herr, Esq., Harrisburg. The commission organized in Philadelphia, April 24, and at that time Judge Johnston was chosen chairman of the commission and its work was outlined. The commission desires to hear from any person suggestions affecting the matters within its scope.

Philadelphia

Personal.—Dr. Asa Copeland has been appointed outdoor physician in the bureau of health.—Dr. James M. Anders has been elected president of the Pennsylvania Society for the Prevention of Tuberculosis.

Drunkenness Statistics.—The arrests for drunkenness in April were 66 per cent. more than for January, February and March, according to Superintendent of Police Mills. For the first three months of the year the average was twenty-four arrests a day, but in April this number rose to forty. For the same period in 1919, the arrests averaged ninety-eight daily. From July 1 until December 31, 1919, the total number of arrests for drunkenness was 6,499, while for the same six months in 1918, the arrests totaled 20,162.

SOUTH CAROLINA

State Board Members Named.—At the annual meeting of the South Carolina Medical Association the following were elected members of the State Board of Medical Examiners: Drs. Joseph T. Taylor, Adams Run; Josiah S. Matthews, Denmark; Frank M. Lander, Williamston; Baxter M. Haynes, Spartanburg; Joseph Roddey Miller, Rock Hill; Julius H. Taylor, Columbia, and George B. Edwards, Darlington; at large, Dr. A. Earle Boozer, Columbia.

New Officers.—At the annual meeting of the South Carolina Medical Association held in Greenville, April 20-21, under the presidency of Dr. Ebenezer W. Pressly, Clover, Columbia was selected as the place of meeting for 1921, and the following officers were elected: president, Dr. Washington P. Timmerman, Batesburg; vice presidents, Drs. William A. Boyd, Columbia, and William W. Fennell, Rock Hill; secretary-treasurer, Dr. Edgar A. Hines, Seneca (reelected).

TEXAS

Women's Auxiliary Organized.—An auxiliary to the Washington County Medical Association has been organized by the wives of the members and the following officers have been elected: president, Mrs. Walter F. Hasskari, Brenham; vice president, Mrs. John W. Tottenham, Jr., Brenham; secretary, Mrs. Oliver S. Moore, Burton, and treasurer, Mrs. Waldo A. Knolle, Brenham.

Personal.—Dr. Edgar L. Gilcreest, Dallas, has returned after two years' service overseas as Major, M. C., American Expeditionary Forces, and has accepted a position in the department of surgery of the University of California, and has moved to San Francisco.—Dr. Otto F. Schoenvogel, Brenham, has been appointed local surgeon for the Houston and Texas Central Railroad, succeeding Dr. Thomas J. Pier, resigned.—Dr. Isaac A. Withers has been appointed city health commissioner of Fort Worth, succeeding Dr. Webb Walker, resigned.

New State Officers.—At the fifty-fourth annual meeting of the State Medical Association of Texas, held in Houston, April 22 to 24, under the presidency of Dr. Robert W. Knox, Houston, Dr. Ira C. Chase, Fort Worth, was elected president to fill the vacancy caused by the death of Dr. Thomas T. Jackson, San Antonio; Dr. Thomas J. Bennett, Austin, was made president-elect; Drs. William S. Miller, Estelline, and Walter Shropshire, Yoakum, were elected vice presidents. Drs. Joseph C. Bloodgood and Lewellys F. Barker, both of Johns Hopkins University, delivered the addresses in surgery and medicine, respectively. Dallas was selected as the next place of meeting.

CANADA

Personal.—Major Fred J. Colling, Toronto, has been awarded the Order of the British Empire for valuable services rendered with the C. E. F. in Siberia. He was for a time senior medical officer to the British Mission in Siberia.

Societies to Meet.—The congress of the Canadian Public Health Association will be held in Vancouver during the week of June 21, under the presidency of Dr. Henry E. Young, Victoria, B. C. During the same week the Canadian Medical Association will hold its annual meeting.

New Medical Organization.—At a meeting of medical men of Ontario engaged in psychiatric work, held April 28, in the Rockwood Hospital for the Insane at Kingston, Ont., it was decided to form the Ontario Medico-Psychological Association. The objects of this organization will be to promote greater interest in nervous and mental cases, social welfare work and defective children, as well as greater care in the selection of immigrants. The following officers were elected: president, Dr. Edward Ryan, superintendent of the Rockwood Hospital for the Insane, Kingston; vice president, Dr. Harvey Clare, medical director of the Ontario Mental Hospital, Toronto; secretary, Dr. Clarence M. Crawford, Ontario Hospital, Whitby; executive committee, Drs. Walter M. English, Hamilton, Goldwin W. Holland, Charles K. Clarke and Robert G. Armour, Toronto, and Nelson H. Beemer, Mimico.

Work of Nova Scotia Red Cross.—The public health course for nurses, organized under the auspices of Dalhousie University, Halifax, in cooperation with other welfare organizations of Halifax, and financed by free scholarships granted by the Red Cross, is to be supplemented by the organization of two traveling clinics. Col. Frank V. Woodbury will devote his entire time to organization of staffs and to the details and equipment of transport for the two traveling clinics that are to go throughout the province during July and August. Trained specialists will accompany these clinics, who will be prepared with outfits and equipment for the removal of tonsils and adenoids and the correction of other remediable defects found in school-children. A dentist with chair and outfit is also included, a tuberculosis specialist, an eye specialist, a nursing corps to assist physicians in their work and to do social service work. The entire personnel will aim to cooperate closely with the local members of the medical profession. The plan also contemplates the transportation of facilities for impressing sanitary lessons, such as educational moving picture films and graphic lessons by projecting lanterns and trained lecturers.

GENERAL

Psychologists to Meet.—The American Medico-Psychological Association will hold its annual meeting at the Hotel Statler, Cleveland, June 1-4, under the presidency of Dr. Henry C. Eymann, Massillon, Ohio.

Research Institute of Baking.—By cooperation between the American Association of the Baking Industry and Dunwoody Institute, Minneapolis, the American Institute of Baking is to be operated at the Dunwoody Institute for three years. The purpose of the institute is to investigate with scientific precision questions relative to the materials and processes used in baking and to cooperate with other organizations in

solving such problems as bakery sanitation, the health of bakery workers, nutritional value of bread and the adoption of valuable diets.

Bequests and Donations.—The following bequests and donations have recently been announced:

Jewish Hospital, \$10,000 for the endowment of a room in memory of himself and wife, and Mount Sinai Hospital, Philadelphia, \$30,000, and Jewish Sanatorium, Eaglesville, \$10,000 by the will of Herman Praeger. Children's Homeopathic Hospital, Philadelphia, \$18,000, Hahnemann Hospital, Philadelphia, \$30,000, for the endowment of six beds, and \$102,000 to be divided between four institutions among which are the Home for Consumptives of the Protestant Episcopal Mission and Home of the Merciful Savior for Crippled Children, by the will of Adeline L. Albright.

Episcopal Hospital, Philadelphia, endowment of a hospital bed as a memorial for members of the order who died during service in the World War by the Order of Sons and Daughters of St. George.

Children's Memorial Hospital, Chicago, \$62,500 by the will of Mrs. Frances H. Mason.

Holds Bogus Diplomas.—Reports published recently in medical journals in Spain state that a "doctor" by the name of José Luis Blanco of Boston does not legally possess the educational qualifications claimed by him. A report states that he first appeared in Spain, claiming to hold a medical diploma from the "University of Philadelphia." The medical society of the town of Orense, where he settled, became convinced that he was not a regularly graduated physician. They discovered that he had practiced in Boston where he claimed to be a graduate of the University of Valladolid, Spain, although reports from that university say that a medical degree had never been conferred on him. A communication from Dr. Walter Bowers of Massachusetts states that about three years ago an investigation of this "doctor" was begun, but that he left the state and has not been heard of since. It is further reported that Sept. 12, 1914, Blanco was convicted in a Boston court and fined \$75 for nonsupport of his wife and two children.

European Physicians Tour America.—A group of eminent European physicians are making a tour of the United States as guests of the National Medical Examining Board. The party consists of Sir Humphry Davy Rolleston of the Royal College of Physicians, London; Col. Holburt J. Waring, Royal College of Surgeons of England, representing the conjoint board of England; Dr. Norman B. Walker, Edinburgh, representing the triple qualification board of Scotland; Prof. G. Roussy and Professor Demorest, representing the Faculty of Medicine of Paris, and Prof. James C. Connell, Kingston, Ont., president of the Dominion Medical Council, Canada. The object of this tour is not only that the members may become acquainted with the members of the profession of this country, but also that they may look into the status of medical education, medical standards, etc., especially. The group were present at the meeting of the Association of Military Surgeons of the United States and at the annual session of the American Medical Association.

FOREIGN

Prize for Prosthetic Appliance.—The Instituto Ortopedico Rizzoli of Bologna offers a prize of 3,500 lire for the best orthopedic work or invention. This is the Umberto I prize, and is open to physicians of any land. For further details address the president of the institute at Bologna. Competition closes Dec. 21, 1920.

Conference on Tuberculosis in the Northland.—The *Norsk Magazin for Lægevidenskaben* announces that the First Tuberculosis Conference of the Northland is to meet at Stockholm, June 28 to 30, this year. Among the subjects to be discussed are the present and desirable laws referring to the tuberculosis; management of the convalescent stage, occupation and colonies; laryngeal tuberculosis, and surgical treatment of pulmonary tuberculosis, including artificial pneumothorax.

Infant Welfare Exhibition in India.—A maternity and infant welfare exhibition was held in Delhi, India, in February at which the proper care of mothers and babies was shown by means of models, charts, slides, pictures, leaflets, lanterns, etc., and prematernity, maternity, infant welfare, childhood, domestic science, hygiene, first aid and home nursing topics were discussed. A public show was also held at which more than 2,000 babies were presented. The exhibition lasted for one month and thousands of women from every part of India were in attendance.

Public Health Congress.—Under the auspices of the Royal Institute of Public Health, a congress on public health will be held in Brussels, May 20 to 24, under the patronage of

King Albert of Belgium. The honorary chairman is Dr. Theophilus J. Kelynack, 37 Russell Square, London, England, and the president is Lord Leverhulme. The congress will be divided into six sections with the following chairmen: state medicine, Dr. J. de Moor; naval, military, tropical and colonial, Gen. O. Wibin; municipal hygiene, F. Hachez; industrial hygiene, Dr. E. Malvez; hygiene and women's work, Dr. D. Gilbert, and bacteriology and chemistry, Drs. Bordet and F. Ranwez.

Foundation of the Cajal Institute at Madrid.—The *Progresos de la Clínica* of Madrid gives the royal decree establishing the Instituto Cajal as a center for scientific research in different branches of biology, and to prepare students to carry on research in other countries. The institute is also to offer facilities to a limited number of foreign research workers, especially those from Latin America, and will invite foreign professors to lecture on their specialties. The new institution will include the laboratories already installed in 1901 for biologic research and the laboratories maintained by the Junta para ampliación de estudios equipped for research on experimental physiology, neuropathology and histology. A new building is planned and the whole will form part of the Instituto Nacional de Ciencias.

Red Cross Council.—At the first general council of the League of Red Cross Societies held in Geneva, Switzerland, March 2 to 8, in the Salle du Grand Conseil of the City Hall, Geneva, twenty-seven of the thirty societies in the council were represented, India, South Africa and Uruguay failing to send representatives. The board of governors was increased by the addition of representatives from Argentina, Australia, Spain, Sweden and Switzerland for a period of four years, and Belgium, Brazil, Canada, Denmark and Serbia for a two-year period. Dr. A. Depage of the Belgian Red Cross was elected chairman of the newly formed medical section of the council and Mr. Willoughby G. Walling, vice chairman of the American Red Cross, was elected chairman of the organization section. The medical section discussed child welfare, tuberculosis, communicable diseases, nursing, medical information, sanitation, vital statistics, social hygiene, malaria, libraries and public health laboratories. Drs. Richard P. Strong, general medical director of the league, and A. Depage of the Belgian Red Cross were appointed medical representatives of the formulating committee to which was submitted the conclusions of the two new sections.

The International Surgical Congress.—It is announced that the Fifth Congress of the International Surgical Association is to be held at Paris, July 19 to 23, 1920, and the addresses on cardiovascular surgery are to be delivered by Tuffier of Paris on the heart; by Sencert of Strasbourg on the large vessels; Jeanbrau of Montpellier on transfusion of blood, and by Alessandri of Rome on the heart and large vessels. The second topic for discussion is surgical radiology, and Régaud of Paris and N. S. Finzi of London will open the subject of treatment of tumors with roentgen and radium rays. The subject of surgical hematology is to be opened by Depage and Goovaerts of Brussels whose address is entitled "Analysis of the Blood and the Biologic Reactions in Surgical Affections." Fractures of the thigh is the fourth topic, and the discussion is to be opened by Patel of Lyon and Major Maurice Sinclair of Fairport. Tetanus, the fifth topic, has been assigned to Donati of Modena and Commins of London. The addresses will be published in time for them to be discussed understandingly. A seven day excursion to the battle fields in France and Belgium is planned (815 francs per person). The notice in our French exchanges adds that the American speakers had not been appointed at the date of writing. The address of the Secrétariat is 72 rue de la Loi, Brussels.

Deaths in Other Countries

Dr. Hector Treub, professor of gynecology and obstetrics at the University of Amsterdam, founder of the Netherlands journal for these specialties, co-editor of the *Geneeskundige Bladen* and frequent contributor to other journals, textbooks, etc., aged 64. The list of his works fills a page in the Surgeon-General's Catalogue. — Dr. D. Schwabach, the otologist of Berlin noted for his time test of hearing by air conduction and bone conduction, aged 73. — Dr. E. Schwabe, director of the pathology institute at the University of Rostock, was shot during the recent rioting there, aged 49. — Dr. V. de la Guardia y Madan, a prominent physician, statistician and medical journalist of Cuba, chief of the vaccine service, aged 70. — Dr. W. Kempner, formerly assistant at the Institute for Infectious Diseases at Berlin, author of works on trypanosomiasis, and, with his wife, Dr. Lydia

Rabinowitsch-Kempner, of works on tuberculosis, aged 50.—Dr. Victor Santos, professor of hygiene at the University of Valladolid.—Dr. N. Zuntz, director of the institute for study of animal physiology at Berlin, and author of numerous works on comparative physiology, aged 73.—Dr. A. Neumann, surgeon to the Friedrichshain Hospital at Berlin, succumbed to lethargic encephalitis, February 21, aged 54.—Dr. F. Hermann, professor of anatomy at Erlangen, aged 61.—Dr. H. Strahl, professor of anatomy at Giessen, aged 63.—Dr. E. I. Rosenthal, professor of internal medicine at Copenhagen, aged 69.

LATIN AMERICA

Department of Radiology in Cuba.—There has been created a department of radiology in the University of Havana, which, for the time being, will be installed in the Hospital Calixto García.

National Laboratory at Santo Domingo.—The municipal council of Santo Domingo has agreed to transfer to the national department of health the municipal laboratory for reorganization as a national laboratory.

School for the Blind in Mexico.—The School for the Blind of the City of Mexico completed its fiftieth anniversary, March 24. The school was founded by Ignacio Trigueros, who also founded a school for the deaf and dumb.

Superior Council of Health in Costa Rica.—The president of Costa Rica has just appointed a superior council of health consisting of three members. The first appointees are Dr. Luciano Beeche, Dr. Carlos Durán and José Maria Soto.

Narcotic Legislation in Santo Domingo.—A recent law enacted in Santo Domingo prohibits the trade in narcotic drugs, and makes it illegal to import, produce, compound, sell, distribute or possess opium or any of its derivatives or synthetic substitutes for opium. The law does not apply to preparations containing less than 2 grains of opium, $\frac{1}{4}$ grain of morphin, or $\frac{1}{8}$ grain of heroin.

Rural Sanitation in Brazil.—An exhaustive report of the rural sanitation work accomplished in the State of Paraná, Brazil, has just been published. The report embraces over 300 pages and has over a hundred illustrations, maps, etc. The work was conducted in cooperation with the Rockefeller foundation; and during the period from September to December, 1919, there were examined by the commission in charge of the work 6,103 individuals, 96.6 per cent. of whom were found infected with some kind of intestinal parasites. A total of 22,679 treatments were furnished, 2,402 homes inspected and thirty-eight lectures given in addition to 6,425 persons vaccinated and 218 malaria cases treated. Dr. H. C. de Souza Araujo is the chief of the federal sanitary commission in charge of this work, which, in its present form of cooperation between the state and the federal government, began in September, 1918.

Vital Statistics of Uruguay.—The department of public health of Uruguay has just published the morbidity and mortality report for the years 1913-1916. It embraces only the reports of cases and deaths due to communicable diseases. During the year 1916 the number of cases of communicable diseases reported in the whole country amounted to 6,818, the number of deaths to 2,641, and the total number of deaths reported to 20,338; the general death rate per thousand of inhabitants was therefore 14.75 during the year 1916. During 1915 the total number of deaths was 16,602, the number of deaths for infectious diseases was 2,008, and the mortality rate per thousand inhabitants 12.33. During the year 1914 the total number of deaths was 15,350, the number of deaths for infectious diseases 1,827, and the mortality rate 11.66 per thousand. During the year 1913 the total number of deaths was 15,374, the number of deaths from infectious diseases 1,721 and the mortality rate 12.01 per thousand. During the year 1913 there were reported 11 cases and 5 deaths from leprosy, 9 cases and 2 deaths from plague and 12 deaths from beriberi; in 1914, 9 cases and 2 deaths of leprosy, 2 cases of plague and 22 cases and 2 deaths of beriberi; during the years 1915, 10 cases and 9 deaths from leprosy, 1 case of plague and 1 case of beriberi; and during the year 1916, 6 cases and 11 deaths of leprosy, 7 cases and 2 deaths from plague and 6 cases of beriberi. The number of deaths for tuberculosis was 1,329 in 1913, 1,540 in 1914, 1,604 in 1915, 1,982 in 1916. No mention is made in the report of how complete these statistics are, nor is any attempt made to explain the comparative increase of the mortality and morbidity in recent years.

Government Services

Marine Hospital Improvements

The Sundry Civil Bill contains provisions for the remodeling of the Marine Hospital at Boston and the erection of medical officers' quarters. There is an appropriation of \$67,700 for this purpose in the bill.

The sum of \$23,000 is appropriated for remodeling the boiler plant and power house at the Marine Hospital at Fort Stanton, New Mexico; \$43,000 is appropriated for an additional hospital ward at the Marine Hospital at Savannah, Ga.

Health Conditions of the Army

There was a moderate increase in the admission rate for sickness, attributable to general causes, during the week ending April 23. Fifty-eight cases of measles were reported, seventeen of these from Camp Taylor, but no other epidemic disease was unusually prevalent. Of thirteen deaths from disease, ten were due to tuberculosis, explained by the fact that many cases of this disease are under treatment in the hospitals as an aftermath of the war. Conditions in the American Expeditionary Forces in Germany are excellent, nine admissions for influenza representing the greatest number of cases of any one epidemic disease.

Medal Awarded

The Distinguished Service Medal has been awarded to Lieut.-Col. Walter C. Montgomery, Medical Corps, U. S. Army, New York City, for exceptionally meritorious and conspicuous service.

"He served with marked distinction as division surgeon of the Twenty-Seventh Division; when confronted with a shortage of personnel he displayed marked initiative and resourcefulness in organizing additional sanitary personnel. During the action along the Hindenberg line, September 25 and 30, by his high professional attainment, sound judgment, and loyal devotion to duty, he so conducted the personnel at his disposal as to provide successfully for the evacuation of 4,000 casualties in four days."

Appropriation for Medical History of War Refused

The House Committee on Appropriations has refused to provide for the publication of the medical and surgical history of the World War. The Surgeon-General of the Army made request that \$150,000 be set aside for the study of the problems of hygiene, medicine and surgery which were involved in the medical care of the Army, based on the knowledge and observations of physicians who guarded the health of our soldiers. The policy of retrenchment in government expenditures is given as the reason for the omission of this appropriation from the Sundry Civil Bill recently reported to the House of Representatives.

Medical Officers in Pay Bill

Medical officers of the Army, Navy and Public Health Service receive substantial increases in pay by the Army and Navy Pay Bill which has passed Senate and House. The following increases are authorized: colonels in the Army, captains in the Navy, and assistant surgeon-general in the Public Health Service, \$600; lieutenant-colonels in the Army, commanders in the Navy, and senior surgeons in the Public Health Service, \$600; majors in the Army, lieutenant-commanders in the Navy, and surgeons in the Public Health Service, \$840; captains in the Army, lieutenants in the Navy and passed assistant surgeons in the Public Health Service, \$720; first lieutenants in the Army, lieutenants, junior grade, in the Navy, and assistant surgeons in the Public Health Service, \$600; second lieutenants in the Army and ensigns in the Navy, \$420; contract surgeons of the Army serving full time will receive the pay of second lieutenants. These increases will be retroactive to Jan. 1, 1920.

Provision is also made for granting commutation of quarters, heat and light for officers of the Navy and Public Health Service as are now granted to commissioned officers of the Army. These benefits are made effective until June 30, 1922.

Provision is also made for transportation at government expense for the wife and dependent children of an officer of the Army, Navy and Public Health Service when such officer is ordered to make a permanent change of station.

Appropriations for Health in Sundry Civil Bill

Under the Sundry Civil Bill, \$46,000,000 is made available for medical and hospital services for beneficiaries of the Bureau of War Risk Insurance; \$4,000,000 for medical services and supplies for beneficiaries of the Public Health Service other than War Risk Insurance patients; \$355,000 for the prevention of epidemics, including smallpox, influenza and infantile paralysis.

The powers and duties of the Interdepartmental Social Hygiene Board are extended. This board was originally created in 1918 as a war measure, to fight venereal disease in the Army and Navy. The Sundry Civil Bill appropriates \$1,015,000 for the continuance of the activities of this board under the direction of Dr. Thomas H. Storey, executive secretary. Of this sum, \$80,000 is for administrative expenses; \$150,000 for assisting the states in protecting the military and naval forces against venereal diseases; \$450,000 to be allotted to the states for the prevention, treatment and control of venereal diseases; \$85,000 for payment to universities and other like institutions to discover more effective medical measures to prevent and treat such diseases; \$250,000 to universities and other organization to develop educational measures for their prevention. The provision is made that such university or organization shall itself first expend a sum twice as large as that received from the federal government.

A Medical Research Council

From time to time, the important work of the Medical Research Committee (a body formed under the National Insurance Act to direct medical researches and for which a grant of money was made) has been reported in *THE JOURNAL*. The government has decided to transform this committee into a new body, termed the Medical Research Council, with an enlarged sphere of duty and with considerably enhanced responsibilities. The council will carry out its functions under a committee of the Privy Council, whose constitution will be the lord president of that body, the minister of health, the secretary for Scotland, and the chief secretary for Ireland, the latter ministers having ex-officio charge of the health of their divisions of the United Kingdom. The Medical Research Council thus becomes a permanent subcommittee of the Privy Council, and under its governing body can enter into all contracts, can hold personal property, and can dispose of this, including parliamentary grants. The Medical Research Council thus obtains direct access to the ministers directly associated with its work; there will be no intervention of any permanent official when the Medical Research Council wishes to urge any measures on those in supreme charge of the health of the United Kingdom. Another point is that the advice of the Royal Society is to be taken in respect of the personnel of the council. The first council consists of the existing Medical Research Committee, and is thus constituted: Mr. C. J. Bond, F.R.C.S., consulting surgeon to Leicester Infirmary; William Bulloch, F.R.S., professor of bacteriology in the University of London; Dr. T. R. Elliott, F.R.S., physician to University College Hospital;

Hon. William Graham, M. P.; Viscount Goschen; Dr. Henry Head, F.R.S.; Gowland Hopkins, F.R.S., professor of biochemistry in the University of Cambridge; Sir William Leishman, F.R.S., director of pathology, Army Medical Service; Noel Paton, F.R.S., professor of physiology in the University of Glasgow, and Hon. E. F. Lindley Wood, M. P. Three members of the council will retire at intervals of two years, and appointments to their vacancies, or to any other vacancies that may casually arise, are to be made by the supervising committee of the Privy Council after consultation with the existing body itself, and with the president of the Royal Society.

The International Health Council

Dr. Addison, minister of health, presided at a luncheon given by the government to the members of the International Health Council. The council was formed, at the suggestion of the ministry of health, to discuss a scheme for the establishment of a health section of the League of Nations. Several meetings have been held in London, and a draft scheme has been agreed on, which will be submitted for approval to the League of Nations. Six countries were represented: America (Surg.-Gen. Rupert Blue), France, Great Britain, Italy, Japan and Poland. The chairman said that a draft constitution had been agreed on, and he hoped that the council would be able to agree primarily on it in a day or two. He hoped the council would do everything possible to promote research of an international character. They were at the beginning of what would prove to be one of the most useful branches of the League of Nations, the stability of which would depend largely on the extent to which it helped to promote the well-being of the different peoples in the world. In that respect the International Health Council would be one of its most important branches.

New Hospital System for Paying Patients

In the *British Medical Journal* is described the foundation at Birmingham of St. Chad's Hospital, an institution for paying patients which is quite novel in this country. A company was formed. It was agreed that the institution should not be advertised in any way and that no patients should be admitted except on the recommendation of a member of the medical staff, and on conditions laid down by the Medical Committee. Patients are divided into two classes: those who pay a composition fee, and ordinary patients. The former receive nursing, home accommodations and all professional attendance, and constitute 90 per cent. of the total admissions. The "composition system" is illustrated by these examples: "C. D., suffering from chronic appendicitis, is accepted for an inclusive charge of \$105. This covers the cost of the operation, the anesthetic, and three weeks' stay in the hospital. The anesthetist receives a direct payment of \$5 from the inclusive fee." "G. H. is admitted with obscure gastric symptoms and stays in the hospital four weeks for a composition charge of \$160. His case requires full investigation, and may call for a consultation between a physician and surgeon, a roentgen-ray examination, and subsequent operation. The cost is covered by the single inclusive payment." The medical staff consists of twenty-three members, each of whom is a consultant and a member of the staff of one of the Birmingham hospitals. An important point is that each member of the staff has the right to call on any other member for consultation in the case of a "composition" patient without fee.

Sex Education and the Birth Rate

The National Birth Rate Commission, whose report will be presented to the prime minister this month, has been reconstituted to continue its inquiry. The terms of reference include consideration of the development and education of

young citizens for worthy parenthood, under the following heads: 1. The various methods of educating boys and girls in sex hygiene before they leave the home and school, and the extent to which graded instruction in sex matters can be usefully given by parents, schoolteachers, ministers of religion, physicians and others. 2. Those influences and conditions which favor or retard the bodily and mental development of the adolescent citizen, so far as these are concerned with the attainment of worthy parenthood. 3. The extent to which worthy ideals of citizenship and parenthood can and should be inculcated by education in its widest sense. Other matters included in the terms of reference are the influence of various industrial occupations on the birth rate; the housing problem; schemes for the "endowment of motherhood" and widows' pensions; problems of migration within the Empire; new discoveries in dietetics; the relation of religious belief to the birth rate; the 1921 census, and the coordination of inquiries in Great Britain and the dominions with those in France, the United States and other countries.

PARIS

April 1, 1920.

Death of Prof. Felix Garrigou

Dr. Felix Garrigou, professor of hydrology at the Faculty of Medicine of Toulouse, died recently at the age of 85. He devoted all of his activities to a study of French mineral waters and to the improvement of our thermal resorts. He was the sole representative of teachers of hydrology in France, for the faculty of Toulouse is the only one with a chair in hydrology. Before the war, this instruction was completed each year by a scientific excursion to one of the hydrologic centers of France.

Recognition of American Services by the Academy of Medicine of Paris

At the meeting of the Academy of Medicine, March 23, Professor Letulle of the Faculty of Medicine gave a very instructive account of the importance of the services rendered to France by the American Red Cross campaign against tuberculosis, during the twenty-two months of its activity (from September, 1917, to July, 1919). The figures of the pledged funds alone, sixteen million francs, indicate the large scale on which the campaign was conceived. Following this address, the Academy of Medicine, on the proposal of Professor Vincent, adopted the following resolution:

"The Academy of Medicine, after hearing the report of Professor Letulle, expresses recognition and gratitude to the American Red Cross for the great services which it rendered to France during the war by the campaign against tuberculosis."

In previous letters (THE JOURNAL, Dec. 6, 1919, p. 1782; Jan. 31, 1920, p. 338) mention has been made of the services of the Rockefeller Commission in aid of the campaign, especially by its educational tours in the provinces. The Academy of Medicine also desired to associate this commission in the tribute to the American Red Cross, and on motion of Dr. Netter, adopted the following resolution:

"The Academy of Medicine is happy to take this occasion to thank the American Commission for the Prevention of Tuberculosis for the services which it has already rendered and continues to render to France."

Institute of Optics

Mention has previously been made of the creation of an institute of theoretic and applied optics, destined to revive in France the manufacture of optical instruments and optical glass. The institute will start its lectures on advanced

optics, April 12. M. Dunoyer, doctor of science, will deliver a course on optical instruments, and M. Chrétien, the astronomer, will conduct the course on calculation of optical combinations. In addition, lectures will be given by M. A. de Gramont on spectroscopy, by M. Appert on the nature and applications of glass, by M. Cotton on the significance of polarized light, by M. Mouton on the microscope and its use in biology and natural science, and by M. de Broglie on the properties of roentgen rays and gamma rays.

Commission on School Hygiene and Physical Education

M. Honnorat, minister of public instruction, has just formed a commission on school hygiene and physical education. The purpose of the commission is an immediate study for early application of the appropriate measures for improving the sanitary conditions of public schools, for combating the diseases of teachers and pupils, especially tuberculosis, for assuring methodical development of the body, and for encouraging and making practical physical exercise and outdoor sports. Among others, Drs. Langlois and Léon Bernard have been appointed members of the commission.

Confederation of Intellectual Workers

Under this name, there is being formed a confederation open to all associations of intellectual workers, for the purpose of representation, coordination and defense of the interests of all those who derive their principal means of existence from intellectual and mental work.

Increasing the Birth Rate

The National Alliance for Increasing the Birth Rate of France recently submitted to all members of the chamber of deputies a scheme of allowances for large families, including these essential clauses: 1. Every head of a family of French nationality, having in charge more than two legitimate or acknowledged children under 13 years, shall receive for the third child an annual allowance of 360 francs, for the fourth 480 francs and for each additional child 600 francs. 2. Children from 13 to 16 years of age, for whom the head of the family has entered into a written contract of apprenticeship, or who, having completed their primary education, devote their activities exclusively to studies at a public educational institution at the expense of their parents shall be considered as children under 13 years.

MEXICO CITY

April 25, 1920.

The Sixth Mexican Medical Congress

As previously announced, the Mexican Medical Congress met at the City of Toluca, April 14-21, and it was a complete success, not only because of the number of physicians present, but also because of the quality of the papers submitted, the number of associations represented, and the resolutions adopted. It would be impossible to summarize in a letter the work accomplished, and I will therefore only mention the papers which attracted most attention.

SUBJECTS DISCUSSED

In Section I the most important papers were Dr. Ocaranza's study of the physiology of the spleen, and Dr. T. López's on the mechanism of phonation; in Section II, Dr. J. J. González's on a new case observed in Mexico of the exotic disease known as "anakhre" or "goundou"; Dr. López Bonaga's on the palliative treatment of epilepsy by intraspinal injections of stovain, and Dr. Perrin's on the Weil-Felix reaction in typhus fever, this paper being illustrated with lantern slides. In the ten cases studied by this author, the blood from typhus fever patients agglutinated the proteus

X 19, while, when the blood serum was normal or from typhoid fever patients, it did not agglutinate the culture. Should these results be confirmed by other investigators, this would strengthen the belief of some clinicians as regards the identity of the Mexican tabardillo with the petechial typhus observed in Europe. Dr. Arroyo discussed the Lange reaction, presenting a summary of 150 cases. Dr. Cicero discussed the present status of our knowledge of the treatment of leprosy, and three members discussed the treatment of syphilis, one of them, Dr. C. Barriere, of Guadalajara, stating his agreement with what we may call the conclusions of the French school—choice of neo-arsphenamin over arsphenamin, nonuse of mercury when arsenicals are employed, and making the treatment chronic and intermittent. From his several years of practice, another speaker advocated the conclusions held by the American school, which seem, as also those of German specialists, to prefer arsphenamin (considering neo-arsphenamin as a less active spirocheticide) and its use together with mercurials, trying in the early cases to obtain a radical cure, which is considered possible in view of the numerous cases of reinfection reported recently. Mention was made of the recent work of A. Knauer of Würzburg, who injects 45 cg. of arsphenamin in the internal carotid for the treatment of general paresis, and stress was laid on the need of controlling the therapeutic results by means of serologic observations. Another paper described the experience of Dr. F. Robles, who, in the Hospital Morelos (for prostitutes), has employed arsphenamin injections in much greater strength than usual, up to 1.2 gm. He has had two deaths in his series of 800 injections, the former occurring in cases in which no large doses were used.

Drs. Fausto Vergara of Tampico and Camarillo of Puebla discussed venereal prophylaxis, the first recommending the creation of a national association, somewhat similar to the American Social Hygiene Association, but resorting also to the use of specific treatment, while the second advocated regulation and urged more scientific treatment of prostitutes, recording in their carnets (record books) not only the present status of their health, but also the results of the Wassermann reaction. Dr. Eliseo Ramírez discussed hereditary syphilis, demonstrating that recently there have been included in this group two classes of children—those who have inherited the infection and those who, while not actually infected, suffer from a hereditary dystrophy. Dr. D. Manuel Vergara, of Puebla, is inclined to believe that Malta fever is prevalent in his city, as shown by his observations, and cultures and inoculations he has made in goats. Dr. Ernesto Cervera discussed the Ronchez reaction, a modification of the Wassermann test recently proposed in France, concluding from his eighty cases that, in general, the modification should not be accepted, as while not more sensitive or specific than the original, its technic is more complicated. Dr. García Rendón presented a monograph on Noguchi's *Leptospira*, claiming to have reproduced the leptospirosis in guinea-pigs, as done elsewhere by Noguchi. Dr. Demetrio López reports that he has obtained good results with Daniélopou's treatment for typhus fever. The last papers presented in this section were by Drs. Alberto Oviedo of Morelia, who thinks he has found a new germ in the blood of typhus fever patients, which he calls *Leptonema*; Manuel Pérez Amador, who compared the results of the fixation of the complement in syphilitic and normal cases, and Vergara, who described the dengue epidemic at Tampico. In the Section on Pharmacology and Therapeutics, mention must be made of Dr. Bulman's study on saccharose, Dr. Gilberto Cicero's paper on blood transfusion, and the address by the pharmacist Donaciano Morales, who attacked the favor shown "patent medicines."

OTHER PAPERS AND PROCEEDINGS

In the Section on Surgery, papers were presented by Dr. Castillo Nájera on the treatment of spermato cystitis through the catheterization of the ejaculatory ducts, and by Professors Ulises Valdés and Malda on surgical technic. In the Section on Ophthalmology there were discussed the action of tuberculin on the eye, the early treatment of glaucoma; cataract extraction by Barraquer's technic; spinal puncture in the treatment of optical neuritis; syphilis as a factor in the ocular complications of typhus fever and influenza, etc. In the Section on Gynecology and Obstetrics, the following papers attracted attention: Dr. U. Valdés, on the differential diagnosis of appendicular and uterine peritonitis; E. Landa's, on occurrence of vertex presentations in Mexico; Dr. Ramírez, on ovarian sclerosis, and Dr. Castañeda's, on criminal abortion in Mexico. Dr. Bonansea presented a paper on the diseases of the cow's udder, and Dr. Pruneda on public health propaganda. In the legal medicine section, Mr. Demetrio Sodi and Drs. García discussed the legal classification of lesions, and Mr. José Torres Torija legal anthropology.

In the general sessions, Dr. Terrés, the president of the congress, discussed the need of confining medical practice to one branch of medical science to obtain the best results, although without neglecting the study of the others. Dr. Amor, dean of the School of Medicine, discussed scleropolycystic ovaritis, and finally Dr. Perrin presented a paper on phagocytosis, illustrated with lantern slides.

Both the federal and local authorities, as well as the local medical society, did everything in their power to make the meeting a success. While the papers presented were not very original, it was seen that an effort was being made to keep in touch with modern developments in medicine.

Among other resolutions the congress adopted the following recommendations: creation of a course in public health in the University of Mexico; establishment of laboratories for diagnostic and research purposes; restrictions on the selling of secret "patent medicines," identical with those on narcotics; employment of arsenicals for the treatment of syphilis, especially as a prophylactic measure, and regulation of the practice of medicine in the whole country.

The next congress will meet in 1922 in the city of Saltillo, Coahuila, and will be presided over by Dr. D. M. Vélez. The secretary will be Dr. Everardo Landa, whose address is 4a Calle del Apartado 130, Mexico City.

Marriages

WILLIAM LAURENCE WHITTEMORE, New York City, to the Hon. Ivy Lorna Jervis of Shanklin, Isle of Wight, England, April 22.

HAROLD DOUGLAS LIVINGSTONE SPENCE, Utica, N. Y., to Miss Mary Gladys Davidson of Hampstead, London, Dec. 9, 1919.

CHARLES WHEATLEY, Lieut., M. C., U. S. Navy, to Miss Mary Frances Shane, both of Washington, D. C., April 5.

WALTER HASKELL HARPER, Spartanburg, S. C., to Miss Marie Christena Peterson of Rodney, Mich., April 22.

LYDIA ALLEN DEVILBISS, Topeka, Kan., to Mr. George Henry Bradford of St. Louis, March 29.

GEORGE BOLLING LEE, New York City, to Miss Helen M. Keeney of San Francisco, April 12.

GILBERT MOMBACH, Cincinnati, to Miss Rosalie Eckstein of New York City, April 20.

DUNCAN PARHAM, Rochester, Minn., to Miss Althea Puech of New Orleans, April 21.

ALBERT F. LESLER to Miss Estelle Weiss, both of New York City, April 19.

HUGH CHAPLIN to Miss Virginia Deems, both of New York City, April 17.

Deaths

Henry Martyn Bannister Ⓢ neurologist and for many years a member of the editorial staff of *THE JOURNAL*, died at his home in Evanston, May 1. He was born July 25, 1844, the son of Rev. Henry Bannister, and was graduated from the National Medical College, Washington, D. C., in 1871. He was a member of the party which made the United States Geological Survey of the territories, including Alaska, in 1872, and on his return located in Chicago. He was one of the founders and joint editor with the late Dr. James S. Jewell of the *Journal of Nervous and Mental Diseases*, and co-author with the late Dr. Daniel R. Brower of a textbook on insanity. For several years he was assistant superintendent of the Kankakee State Hospital. He had been an invalid for many years on account of arthritis deformans, but still kept up his literary work so far as he could. He was a man wonderfully well read in medical science, and was learned, not only in his own specialty but in the broad fields of literature and science; a man of delightful personality and beloved by all who knew him.

Sidney Freeman Wilcox, New York City; New York Homeopathic Medical College, New York City, 1880; aged 64; for twenty-two years professor of clinical surgery in the New York College and Hospital for Women, and later emeritus professor; consulting surgeon to the New York Hospital for Women, New York Ophthalmic Hospital, Laura Franklin Free Hospital for Children, Memorial Hospital for Women and Children, Brooklyn; St. Mary's Hospital, Passaic, N. J., Grace Hospital, New Haven, Conn., and Wesson Hospital, Springfield, Mass.; while operating in Thrall Hospital, Middletown, N. Y., April 20, died from cerebral hemorrhage.

Frederick C. A. Kellam, Jr. Ⓢ Major, M. C., U. S. Army, Washington, D. C.; Atlanta College of Physicians and Surgeons, 1909; aged 38; who was commissioned first lieutenant, Medical Reserve Corps, in 1911; graduated from the Army Medical School, and commissioned lieutenant, M. C., 1912; promoted to captain in 1915, to major in 1917, and to lieutenant-colonel (emergency), Oct. 8, 1918; died in the Walter Reed General Hospital, Takoma Park, D. C., April 5.

Charles Dudley Prescott, New Bedford, Mass.; Dartmouth Medical School, Hanover, N. H., 1867; aged 75; a member of the Massachusetts Medical Society; president of the Bristol County Medical Society in 1888 and 1889; quarantine physician and health officer of New Bedford from 1879 to 1881; from 1873 to 1879 physician at house of correction; a member of the staff of St. Luke's Hospital since 1884; died, March 22.

Henry Leland Akin Ⓢ Omaha; John A. Creighton Medical College, Omaha, 1901; aged 47; major, M. R. C., U. S. Army, with two years' service in France, in charge of a hospital at LaRocheville, and discharged July 9, 1919; professor of gastroenterology, and of medicine and clinical medicine in his alma mater; died in his garage, April 20, from the effects of carbolic acid, self-administered, it is believed, with suicidal intent.

Howard A. McDonald, Prairie Home, Mo.; Beaumont Hospital Medical College, 1898; aged 45; formerly assistant secretary of the Missouri State Medical Association, and secretary of the surgical section of that association, and president of the John McDowell Medical Society; who had been a patient at State Hospital No. 3, Nevada, Mo., for several months, died in that institution, April 18.

John Henry Barbat Ⓢ San Francisco; University of California, San Francisco, 1888; aged 57; formerly president of the San Francisco Board of Health and in 1918 president of the Medical Society of the State of California; member of the State Board of Medical Examiners from 1894 to 1898; lecturer on surgery in his alma mater; died, April 22.

Omar Adrian Kell, Salem, Ill.; Barnes Medical College, St. Louis, 1900; aged 48; a member of the Illinois State Medical Society; for several years resident neurologist at the Kankakee State Hospital; once mayor of Salem; died in the Missouri Baptist Sanitarium, St. Louis, April 11, from septicemia, due to an infection of the thumb.

Alfred Wharton, St. Paul; University of Pennsylvania, Philadelphia, 1857; aged 84; surgeon of U. S. Volunteers during the Civil War, and surgeon of the Sixth Minnesota Volunteer Infantry during the Indian outbreak of 1862; died at the home of his daughter in St. Paul, April 13.

Francis Achilles Davis Ⓢ Chicago; Northwestern University Medical School, Chicago, 1899; aged 45; captain, M. R. C., U. S. Army, and discharged Jan. 20, 1919; formerly assistant professor of medicine in his alma mater, and a member of the medical staff of Wesley Memorial Hospital; died, May 3, from uremia and pneumonia.

William Varian, Buffalo; Pennsylvania Medical College, Philadelphia, 1854; aged 87; major and surgeon of U. S. Volunteers during the Civil War; at one time president of the Medical Society of the State of Pennsylvania; for several years secretary of the Titusville (Pa.) Board of Health; died, April 12.

Arthur Springer Hagan, Uniontown, Pa.; Western Pennsylvania Medical College; Pittsburgh, 1901; aged 41; coroner of Fayette County for two terms; a member of the Medical Society of the State of Pennsylvania, and a member of the local board of education; died, March 31, following an operation.

Charles F. Lynch, Chicago; Bennett Medical College, Chicago, 1913; aged 33; major, M. O. R. C., U. S. Army; formerly district health officer at Aberdeen, S. D.; died in Presbyterian Hospital, Chicago, April 28, from septicemia following an infected wound of the finger.

John Edward Kidd, Wyoming, Ont.; Western University, London, Ont., 1909; aged 40; while driving over a grade crossing in his automobile, March 18, was struck by a train receiving injuries from which he died in Victoria General Hospital, London, March 21.

Christopher P. Linhart, Columbus, Ohio; Western Reserve University, Cleveland, 1882; aged 59; a member of the Ohio State Medical Association, and a specialist in diseases of the eye, ear, nose and throat; city school physician; died, April 15, from pneumonia.

Lewis Jasper Keeling, Atlanta, Ga.; Atlanta (Ga.) Medical College, 1914; aged 27; lieutenant, M. C., U. S. Army, and discharged, Dec. 13, 1918; was instantly killed, April 24, in a fall down an elevator shaft in the building in which he had his office.

Ernest Edgar Beckett, Seattle; Hering Medical College, Chicago, 1895; aged 47; a member of the Washington State Medical Association; captain, M. C., U. S. Army, and discharged Dec. 6, 1918; died, April 9, from cerebral hemorrhage.

Alexander Wallace Aiken Ⓢ Chicago; University of Toronto and Trinity Medical College, Toronto, 1895; aged 49; died in the Presbyterian Hospital, Chicago, April 27, from septicemia following an infected wound of the finger.

Walter G. Spiess Ⓢ Philadelphia; Medico-Chirurgical College of Philadelphia, 1903; aged 40; a member of the staff of the Kensington Dispensary for Tuberculosis; died, April 23, from encephalitis.

James Dismurkes Smith, Nelson, Mo.; Missouri Medical College, St. Louis, 1887; aged 60; a member of the Missouri State Medical Association; died, April 14, from cerebral hemorrhage.

Robert Emerson, El Paso, Texas; University of Illinois, Chicago, 1898; aged 63; for twenty years a resident of Chihuahua City, Mexico; died, February 23, from senile gangrene.

William L. Downey, Wenona, Ill.; Medical Department University of Iowa, Keokuk, 1865; aged 82; a veteran of the Civil War; for many years a druggist; died, April 7.

Fordyce Worth, Hesper, Iowa; Bennett College of Eclectic Medicine and Surgery, Chicago, 1870; aged 88; died in LaCrosse, Wis., March 14, from pneumonia.

William L. Griffin, Lamar, Mo. (license, Missouri, 1883); aged 82; a practitioner for fifty-four years; a veteran of the Civil War; died, April 1, from paralysis.

Ezra C. Harris, Springfield, Ohio; Starling Medical College, Columbus, Ohio, 1876; aged 75; a veteran of the Civil War; died, April 17, from heart disease.

John Henry Williard, Lewistown, Mont.; Medical College of Ohio, Cincinnati, 1869; aged 73; died at the home of his sister in Lancaster, Ohio, March 29.

Carl W. J. Specht, Fairview, Okla. (license, Oklahoma, 1908); aged 66; a practitioner for thirty-four years; died in St. Louis, April 6, from pneumonia.

Franklin A. Weatherford Ⓢ Chicago; College of Physicians and Surgeons, Chicago, 1895; aged 54; died, May 2, from cerebral hemorrhage.

Carl Kirschner, Erie, Pa.; Medico-Chirurgical College of Philadelphia, 1903; aged 42; died, April 19, from pneumonia.

Correspondence

PRIDE IN AN EXCELLENT TYPHOID RECORD

To the Editor:—So much criticism has been directed against the sanitation of rural districts that the extremely low typhoid death rate in Los Angeles County deserves special publicity.

Comparing the deaths in Los Angeles County rural districts (unincorporated section only) with the rates appearing in the eighth annual report on the prevalence of typhoid in larger cities (*THE JOURNAL*, March 6, 1920, p. 672), we discovered that the death rate was actually lower for our county than for the average of sixty cities during 1919. Many of the cities had a rate as high as 15 per hundred thousand, while the average was 4.2 per hundred thousand. The rate for Los Angeles County was 4 per hundred thousand population, as of July 1, 1919. During the year 1918 there was not a single death recorded from typhoid fever in the rural districts. During 1919, however, we had six deaths and twenty-six cases, the increase being due to the insanitary conditions prevailing among the Japanese vegetable growers.

The Los Angeles County Health Department comprises a bureau of twenty-six persons, and we are very proud of this record, which should be an encouraging note to those who continually decry the insanitary conditions in the rural districts.

J. L. POMEROY, M.D., Los Angeles.

County Health Officer.

A COMPARISON OF THE HUTCHINSON AND SPILLER OPERATIONS FOR THE RELIEF OF TRIGEMINAL NEURALGIA

To the Editor:—The radical operation for the treatment of trigeminal neuralgia is exceedingly satisfactory in its results.

Fig. 1.—Reproduction (reduced) of illustration bearing the legend: "Tic douloureux. Physiological extirpation of the Gasserian ganglion. Showing site of flap incision for Spiller-Frazier operation, and the blepharorrhaphy of the left eye for trophic ulceration of the cornea. In this case the conspicuous scar on the side of the face and the depression left by the division of the zygoma are shown."

Section of the sensory root, as a means of affording permanent relief, has been acknowledged almost universally as the accepted procedure. The technic as elaborated has well nigh reached a stage of perfection, in that the cosmetic results leave nothing to be desired and we now are able to conserve

the motor root. Hutchinson, however, still advocates the resection of the outer two thirds of the ganglion. In his recent monograph on "Facial Neuralgia and Its Treatment" there are three references to what he calls the Spiller-Frazier operation, one of which is incorrect, and the other two misleading.

On page 118 it is stated that the operation is "more difficult, dangerous and uncertain than the extradural method."

Fig. 2.—Cosmetic results in patient after operation. The incision is entirely within the hair line, hidden from view.

Our experience with the operation at the clinic of the University Hospital has proved quite conclusively that the operation is not more difficult than methods which have for their object the total or partial removal of the ganglion; and, comparing the mortality of this clinic with that of Mr. Hutchinson's, it could hardly be said to be "more dangerous." Mr. Hutchinson, quoting the statistics from his own and Sir Victor Horsley's experience with 200 cases and a mortality under 5 per cent., characterizes the results as "surely satisfactory enough." In the last 129 cases in which the technic we now use was applied, there has been but one death, a mortality of 0.7 per cent. In this case the patient, ten days after the operation, when out of bed and about ready for discharge, had an apoplectic stroke. Whatever else may be said in comparison of the Hutchinson and the Spiller operation, the latter should not be presented to the medical public as "more dangerous."

A greater injustice is contained perhaps in the second reference. An illustration (Figure 1) is reproduced with the legend: "Tic douloureux. Physiological extirpation of the Gasserian ganglion. Showing site of flap incision for Spiller-Frazier operation, and the blepharorrhaphy of the left eye for trophic ulceration of the cornea. In this case the conspicuous scar on the side of the face and the depression left by the division of the zygoma are shown."

If the reader will compare Figure 1 with Figure 2 (photograph of patient operated on by Dr. Frazier) the misrepresentation is apparent. It will be seen in Figure 2 that the scar is entirely hidden, concealed within the hair line; furthermore, it has never been my practice to resect the zygoma.

On page 117, Hutchinson credits the operation on the sensory root, as a substitute for gasserectomy, to Horsley who in 1891 divided the sensory root behind the ganglion in only one case, the patient dying from shock seven hours after the operation. "It appears," he writes, "that for many years this method was not again attempted. In 1901 and 1902, however, Spiller and Frazier again brought it forward." The dates

are correct, but it would have been more nearly the truth had he amplified his statement to include the following: (a) that Horsley, so far as one can ascertain from his publications, never repeated the operation and presumably abandoned it; (b) that the method of approach in Horsley's case was radically different and more difficult than that proposed by Spiller and Frazier (Horsley approached the sensory root by elevating the temporosphenoidal lobe after reflecting a dural flap); (c) that Spiller's recommendation was supported by a series of animal experiments which proved convincingly that the results would be permanent as the root could not regenerate itself; (d) that the claims of superiority of this operation, as safer than gasserectomy, were not made until proved by actual experience on the operating table, and (e) that, as a result of the combined experimental and clinical evidence, this operation (properly designated as the "Spiller" and not as Hutchinson styles it, the Spiller-Frazier method) has been recognized in all civilized countries as the appropriate radical procedure in the treatment of trigeminal neuralgia.

CHARLES H. FRAZIER, M.D., Philadelphia.

"QUININ IN INFLUENZAL PNEUMONIA"— USEFULNESS OF CALOMEL

To the Editor:—Two articles in THE JOURNAL, April 24, 1920, attracted my attention:

Dr. A. J. Caffrey of Milwaukee (p. 1166) writes on the value of quinin in influenzal pneumonia. During the great epidemic of 1918, while in Macedonia with the troops, I personally treated, and saw treated by my colleagues, a large number of cases of influenza and of bronchopneumonia. On account of the prevalence of malarial infection, many of these patients were vigorously plied with quinin dihydrochlorid. My own routine was 15 grains thrice daily. I can say with confidence that I saw no benefit from the administration of quinin in either influenza or bronchopneumonia.

Dr. A. E. Goodwin of Jackson, Miss. (p. 1163) condemns the free use of calomel as a cathartic, and cites two cases to support his argument. A man, aged 50, after taking 2 grains of calomel, developed extensive gangrene of the tongue, gums and palate which caused his death. In the second case, a child, aged 5 years, after a dose of calomel had diarrhea, salivation and sloughing of the cheek. From the history I regard it as a case of cancrum oris. The evidence of mercurial poisoning in these two cases is to me inconclusive, and would not influence me to discard a drug which I find invaluable.

JAMES CAMPBELL, M.B., CH.B. (ABERD.),
Washington, D. C.

"SPIRITS AND THE MEDICAL MIND"

To the Editor:—I have been hoping that some one else would do this; but, others failing, I desire to protest against the attitude of THE JOURNAL as depicted in the recent editorial on "Spirits and the Medical Mind" (THE JOURNAL, March 27, 1920, p. 890). If I may be very blunt that I may be very brief, I would protest against a spokesman for the profession who fails to distinguish between the London Society for Psychic Research and the spiritualistic cult. He fails, too, in accounting for the spread of the latter cult, when he ignores the item of phenomena, the one constant feature that wins proselytes to a system that has nothing else at all to support it. If these phenomena can be shown to be subjective, such a showing would be praiseworthy; but it is not serving any good purpose to simply call for the alienist. It is a question of fact, not of doctrines; of natural forces rather than of belief in the supernatural. "A mind adjusted to set up an adequate resistance" in advance

is not an open and a judicial mind, and it would be more in keeping with the dignity of the American Medical Association to make "a patient analysis of the evidence to see what it really shows." There are physicians to whom medicine means more than the daily, diagnostic thought-habits of practicing specialists; who keep in touch with the progress of the world in all lines; who enjoy the large view of the present day, and hope that the darkness that limits human understanding may be pushed back for another gain in their generation. Such physicians are not uninterested in physics or philosophy. Those who have accepted the Einstein revelation may talk of our universe as confidently as of our world, and those who studied last year's books, from Haeckel to Whitman, may feel certain that nothing that ever had a real existence was ever lost. All will agree that the world grows. And the American Medical Association grows. Let it not hide now from "unrecognized forces." I beg to propose a Committee on Psychical Research as an addition to the active departments of this association. It might have a perfectly legitimate and fairly permanent occupation in the exposing of frauds. Then, perhaps, it might start a card index for communications—no sources barred—and assist the British, on the firing line again, in the newest phase of the oldest campaign in which mankind has ever engaged.

JAMES JOHNSTON, M.D., Bradford, Pa.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

BENZYL AND TOLYL

To the Editor:—1. My copy of the American Illustrated Medical Dictionary states that "benzene," C_6H_6 , is called also "benzyl"; it states under "benzyl" that it is C_7H_7 . Please clear up this apparent inconsistency.

2. I believe that the proper name for this C_7H_7 group should be "tolyl" to distinguish it from C_6H_5 , and that the proper nomenclature of the substances developed therapeutically by Macht should be toluyl benzoate, toluyl acetate and toluyl alcohol; and that benzyl benzoate, benzyl acetate and benzyl alcohol denominate entirely different substances.

3. In your abstracts of medical journals you recently mentioned benzyl carbinol as having been found more suitable for local anesthesia than benzyl alcohol. I have not been able to secure this through a certain large chemical and drug house, and would appreciate any suggestions you could offer as to where a supply of benzyl carbinol might be obtained.

I. F. S.

ANSWERS.—1. The symbol C_7H_7 may stand for either of two radicals derived from toluene. In one of these, one hydrogen atom of the benzene nucleus (C_6H_5) has been replaced by the methyl group (CH_3) and another hydrogen atom has been

removed, leaving an uncombined linkage, thus: $C_6H_4-CH_3$. This is called "tolyl" (toluyl). In the other instance, only one hydrogen atom of the benzene nucleus has been removed, that having been replaced by the methyl group (CH_3) and one hydrogen in the methyl group having been removed, leaving an uncombined linkage, thus $C_6H_5-CH_2-$. This form is called "benzyl" to denote its relationship to benzoic acid.

2. If hydroxyl (OH) be attached to the tolyl radical, i. e., the OH group being attached to the benzene nucleus, the compound is not an alcohol but a phenol. Thus, tolyl hydroxid

is cresol, $C_6H_4(OH)-CH_3$. On the other hand, if the OH group

be attached to the benzyl group ($C_6H_5CH_2$), an alcohol, benzyl alcohol ($C_6H_5CH_2OH$), results. Benzyl alcohol is also called phenyl methylol and phenyl carbinol.

3. Benzyl carbinol is synonymous with phenyl ethyl alcohol. It is a constituent of oil of rose and may be purchased under the second name of dealers in synthetic perfumes.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

ARKANSAS: Little Rock, May 11-12. Sec. Regular Bd., Dr. I. J. Stout, Brinkley. Sec. Eclectic Bd., Dr. C. E. Laws, Fort Smith.

DELAWARE: Wilmington, June 15-17. Pres. Medical Council, Dr. H. W. Briggs, 1026 Jackson St., Wilmington.

FLORIDA: Jacksonville, June 14-15. Sec., Dr. Wm. M. Rowlett, Citizens Bank Bldg., Tampa.

GEORGIA: Atlanta, June 9-11. Sec., Dr. C. T. Nolan, Marietta.

HAWAII: Honolulu, May 10-14. Sec., Dr. R. W. Benz, 1141 Alakea St., Honolulu.

ILLINOIS: Chicago, June 14-17. Director, Mr. Francis W. Shepardson, Springfield.

KANSAS: Topeka, June 15-16. Sec., Dr. H. A. Dykes, Lebanon.

KENTUCKY: Louisville, May 17. Sec., Dr. A. T. McCormack, 532 W. Main St., Louisville.

LOUISIANA: New Orleans, June 10-12. Sec., Dr. E. W. Mahler, 141 Elk Place, New Orleans.

MARYLAND: Baltimore, June 15. Sec., Dr. J. McP. Scott, 137 W. Washington St., Hagerstown.

MASSACHUSETTS: Boston, May 11-13. Sec., Dr. Walter P. Bowers, Room 144, State House, Boston.

MICHIGAN: Ann Arbor, June 8-10. Sec., Dr. B. D. Harrison, 504 Washington Arcade, Detroit.

MINNESOTA: Minneapolis, June 1-4. Sec., Dr. Thos. McDavitt, 539 Lowry Bldg., St. Paul.

MISSOURI: St. Louis, June 14-16. Sec., Dr. Geo. H. Jones, State House, Jefferson City.

NATIONAL BOARD OF MEDICAL EXAMINERS: Philadelphia, May 19-26. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia.

NEBRASKA: Lincoln, June 9-11. Sec., Department of Public Welfare, Mr. H. H. Antles, Lincoln.

NEW JERSEY: Trenton, June 15-16. Sec., Dr. Alexander MacAlister, State House, Trenton.

NEW YORK: New York, Albany, Syracuse, Buffalo, May 18-21. Assistant, professional examinations, Mr. Herbert J. Hamilton, Education Bldg., Albany.

NORTH CAROLINA: Raleigh, June 21. Sec., Dr. H. A. Royster, 423 Fayetteville St., Raleigh.

OHIO: Columbus, June 8-11. Sec., Dr. H. M. Platter, State House, Columbus.

SOUTH CAROLINA: Columbia, June 22. Sec., Dr. A. Earle Boozer, 1806 Hampton St., Columbia.

TENNESSEE: Memphis, Nashville and Knoxville, June 11-12. Sec., Dr. A. B. DeLoach, 1001 Exchange Bldg., Memphis.

TEXAS: Galveston, June 22-24. Sec., Dr. Thos. J. Crowe, Trust Bldg., Dallas.

VIRGINIA: Richmond, June 22-25. Sec., Dr. J. W. Preston, McBain Bldg., Roanoke.

WYOMING: Cheyenne, June 7-9. Sec., Dr. J. D. Shingle, Cheyenne.

Iowa January Report

Dr. Guilford H. Sumner, secretary of the Iowa State Board of Medical Examiners, reports that 15 candidates were licensed by reciprocity at the meeting held Jan. 22, 1920. The following colleges were represented:

College	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Chicago Coll. of Med. and Surg.	(1915), (1916), (1917)		Illinois
Northwestern University	(1917), (1918)		Illinois
Rush Medical College	(1919)		Wisconsin
University of Minnesota Medical School	(1917)		Minnesota
St. Louis University	(1918)		Missouri
John A. Creighton Med. Coll.	(1913), (1916), (1918, 2), (1919)		Nebraska
University of Nebraska	(1919)		Nebraska
University of Virginia	(1897)		Georgia

Missouri January Examination

Dr. George H. Jones, secretary of the Missouri State Board of Health, reports the written examination held at St. Louis, Jan. 12-14, 1920. The examination covered 14 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 21 candidates examined, 18 passed and 3 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Hahnemann Med. Coll. and Hosp. of Chicago	(1898)		75.8
Harvard University	(1917)		77.9
Barnes Medical College	(1907)		76.1
Kansas City Medical College	(1905)		79.4
St. Louis College of Phys. and Surgs.	(1918)		75.1
St. Louis University	(1920) 79.8, 80.1, 83.1, 83.1, 84.7, 84.9, 88.1.		
Washington University	(1917) 83.1, (1918) 83.1, 84.8, (1919)		83.1
Columbia University	(1916) 90.7, (1917)		89.7

College	FAILED	Year Grad.	Per Cent.
National University of Arts and Sciences	(1918)		*
St. Louis College of Phys. and Surgs.	(1918, 2)		*

College	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Chicago College of Med. and Surg.	(1914, 2), (1917)		Illinois
	(1918)		W. Virginia

Meharry Medical College	(1915), (1917)	Kentucky
University of Munich	(1914)	Illinois

* No grade given.

New York January Report

Mr. Herbert J. Hamilton, assistant, professional examinations, New York State Board of Medical Examiners, reports that four candidates were licensed by endorsement of their credentials from Jan. 5 to Jan. 19, 1920. The following colleges were represented:

College	ENDORSEMENT OF CREDENTIALS	Year Grad.	Endorsement with
Medico-Chirurgical College of Philadelphia	(1910)		Penna.
Woman's Medical College of Pennsylvania	(1909)		New Jersey
University of Virginia	(1916)		Virginia
National University, Athens	(1904)		Indiana

North Dakota January Examination

Dr. George M. Williamson, secretary of the North Dakota State Board of Medical Examiners, reports the oral, written and practical examination held at Grand Forks, Jan. 6-9, 1920. The examination covered 14 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 8 candidates examined, 6 passed and 2 failed. Six candidates were licensed by reciprocity. One candidate was licensed on a certificate from the National Board of Medical Examiners. The following colleges were represented:

College	PASSED	Year Grad.	Number Licensed
Northwestern University	(1918)		83
Rush Medical College	(1919)		85.5
University of Illinois	(1918)		87
University of Minnesota Medical School	(1917) 81.3, (1919)		81.5
Manitoba Medical College	(1908)		78

College	FAILED	Year Grad.	Number Licensed
University of Vermont	(1908)		72
Chicago College of Medicine and Surgery	(1916)		64

College	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Chicago College of Medicine and Surgery	(1908)		Illinois
Northwestern University	(1916), (1917, 2)		Illinois
Rush Medical College	(1915)		Illinois
University of Minnesota Medical School	(1911)		Minnesota

College	ENDORSEMENT OF CREDENTIALS	Year Grad.	Endorsement with
Rush Medical College	(1915)		N. B. M. Ex.

Pennsylvania January Report

Dr. Thomas E. Finnegan, secretary of the Pennsylvania Bureau of Medical Education and Licensure, reports the written and practical examination held at Philadelphia, Jan. 13-15, 1920. The examination covered 5 subjects and included 50 questions. An average of 75 per cent. was required to pass. Of the 95 candidates examined, 81 passed and 14 failed. The following colleges were represented:

College	PASSED	Year Grad.	Number Licensed
Howard University	(1906)		1
Atlanta Medical College	(1916)		1
Rush Medical College	(1917)		1
University of Louisville	(1914), (1915)		2

Vermont February Report

Dr. W. Scott Nay, secretary of the Vermont State Board of Medical Registration, reports the written and practical examination held at Burlington, Feb. 10-12, 1920. The examination covered 12 subjects and included 180 questions. An average of 75 per cent. was required to pass. Two candidates were examined, both of whom passed. The following college was represented:

College	PASSED	Year Grad.	Per Cent.
University of Vermont.....	(1913)	88.7, (1919)	79.6

Book Notices

THE OXFORD MEDICINE. ADVANCE PAGES. Edited by Henry A. Christian and Sir James Mackenzie. Volume 1, Part 5. Paper. New York: Oxford University Press, 1920.

The first article is a well written, carefully thought out, philosophic discussion of the rationale of clinical diagnosis, by L. F. Barker. The origin, development and aims of diagnosis are clearly set forth, together with its relations to other branches of medicine as well as to other closely related sciences, especially the so-called premedical sciences. Among the latter, by the way, Barker would include sociology, psychology and—as a special branch of biology—anthropology. The article is well worth reading by student or practitioner; it views diagnosis from an angle not often considered. We should like it better were it a little more condensed. This might in part be accomplished by the shortening of lists of instruments, diseases, parts of the body to be investigated by the roentgen ray, etc. The intent of the article is not to furnish a textbook of clinical diagnosis with a complete or encyclopedic cataloging of the methods or the technic of diagnosis. These lists could well be illustrative, therefore, with something left to the imagination of the reader, who will be flattered at the assumption that he knows the rest rather than annoyed that the writer has at times deemed it necessary to name things of such elementary character that they ought to be common knowledge.

H. A. Christian, in ten pages, discusses in a general way tests of function. The saving feature is the bibliography, which points the reader to some of the more important origi-

nal articles. It is clearly impossible to discuss with thoroughness in such limited space important subjects like the tests for renal, gastric and circulatory function. Gastric function in a little more than one page and circulatory in two pages are handled in scant, stepmotherly fashion. Peabody's article on respiration in disease is excellent. Du Bois considers the calorimetric methods of study of disease, and gives references so that those interested may find details that would be out of place in his article, which takes up only the general topic.

THE MEDICAL ASPECTS OF MUSTARD GAS POISONING. Alfred Scott Warthin, Ph.D., M.D., Professor of Pathology of the University of Michigan, and Carl Vernon Weller, M.S., M.D., Assistant Professor of Pathology, University of Michigan. Cloth. Price, \$7. Pp. 267, with 156 illustrations. St. Louis: C. V. Mosby Company, 1919.

If the complete story of the scientific activities carried on in this country as part of the broad program for the winning of the war should ever be published, the scope of the work under way under the Chemical Warfare Service and the amount of the work already accomplished at the time of the armistice would undoubtedly astound all those not intimately connected with it. An important part of this work concerned medical problems, especially the pathology and pharmacology of the action of gases in use or proposed for introduction in offensive warfare. While much of this work was done in Washington, numerous problems were investigated in other laboratories throughout the country, as part of a program of cooperative research that has since become perpetuated through the continuance of the National Research Council as a peace-time organization. The work reported by Warthin and Weller was in part done under these auspices, and most of it has already been described in articles in the *Journal of Laboratory and Clinical Medicine*. These articles have now been collected and somewhat expanded to form this volume, and a brief discussion of the properties and effects of most of the gases used by the Germans serves as an introduction to the discussion of "mustard gas" and its properties.

This famous poison, undoubtedly one of the most important used in the war, has especially striking toxic effects which are discussed at length, both from the experimental side and from the point of observations on human material. As is now generally understood, this substance has no relation to mustard beyond a slight similarity of smell, being dichloroethylsulphid. We owe it to the German chemist Victor Meyer, who learned of its toxic properties as soon as it was first produced in his laboratory, by virtue of its effects on the assistant who worked with it. Experiments soon established its capacity for damage to living tissues, and the information thus obtained was utilized thirty years later with great effect by the organizers of "Schrecklichkeit."

The monograph of Warthin and Weller gives in great detail the pathologic effects of mustard gas on experimental animals, the lesions in human cases, a clinical study of thirty cases arising in manufacturing plants, and both experimental and clinical observations on treatment. An extensive bibliography completes this important contribution to what, it is to be hoped, is a closed chapter in human experience.

DIE THERAPIE DER HAUT- UND VENERISCHEN KRANKHEITEN, MIT BESONDERER BERÜCKSICHTIGUNG DER BEHANDLUNGSTECHNIK FÜR AERZTE UND STUDIERENDE. Von Prof. Dr. J. Schäffer. Cloth. Price, 22 marks. Pp. 485, with 87 illustrations. Berlin: Urban & Schwarzenberg, 1919.

This handbook, the first edition of which appeared in 1915, is the elaboration of a series of articles prepared for the *Medizinische Klinik* in 1913 under the title, "Dermatotherapeutische Winke für den Praktiker." The book is typical of the handbooks on special subjects of which there are so many in Europe. It is written in clear and concise style, yet is sufficiently comprehensive. Practically every method of treatment used in dermatology and venerology is described. The formulas are numerous, but one is struck by the fact that a large number contain drugs having trade names which are not familiar to American readers at the present time. As the physician must be able to arrive at a diagnosis before availing himself of the methods of treatment described, it seems obvious that a man with enough dermatologic training to make use of the book would not need it.

Miscellany

THE FIRST PHARMACOPEIA PUBLISHED IN THE UNITED STATES

ALEXANDER G. BROWN, JR., M.D.
RICHMOND, VA.

The occasion of the approaching tenth decennial session of the United States Pharmaceutical Convention, May 11, at Washington, D. C., calls to mind a fact probably known to few physicians and pharmacists, that the first pharmacopeia published in the United States was in the year 1778. It was written in Lititz, Lancaster County, Pa., during General Washington's Valley Forge encampment and campaign about Philadelphia in 1777-1778. This first pharmacopeia was written for the use of Continental Army hospitals. As far as known, only two copies of this original pharmacopeia exist, one being the property of the estate of Charles A. Heinitsch, a druggist of Lancaster, Pa., and the other being in the Library of the Surgeon-General's Office in Washington. This publication was written entirely in Latin. It contained thirty-two pages. It was printed by Charles Cist of Philadelphia.

The title page may be of interest:

PHARMACOPOEIA
Simpliciorum & Efficaciorum
in usum
Nosocomii Militaris
ad exercitum
Foederatarum Americae Civitatum
Pertinentis;
Hodiernae Nostrae Inopiae
Rerumque Angustiarum,
Feroei hostium saevitiae, belloque
crudeli ex inopinato patriae nostrae illato debitis,
Maxime Accommodata.
Auctore Gulielmo Brown, M.D.
Editio Altera
Philadelphiae
Ex Officina Caroli Cist
MDCCCLXXXI.

The author, Dr. William Brown (1752-1792), was the grandson of Dr. Gustavus Brown (1689-1765), of Port Tobacco, Md., and the son of Rev. Richard Brown of the Colonial Episcopal Church of Maryland. Although born in Haddingtonshire, Scotland, while his parents were temporarily residing abroad, he was an American. He graduated and received his M.D. degree in 1770, from the University of Edinburgh. The subject of his thesis was "De Viribus Atmosphaerae." After his graduation, Dr. Brown settled in Alexandria, Va. He soon attained a high professional standing, and became intimate with many of the leading men of the day, among them Washington, Jefferson and Madison. At the beginning of the Revolution, Dr. Brown entered the service of his country as surgeon to Colonel Woolford's regiment of Virginia troops but, Sept. 20, 1776, was elected assistant to Dr. Shippen, a chief physician of the Continental Army. On the recommendation of Gen. Hugh Mercer, one of Washington's greatest generals, he was elected by congress, July 2, 1777, to be physician-general of the middle department of the Continental Army in place of Dr. Benjamin Rush (1745-1813), which position

he resigned, July 21, 1780, returning to private practice. On his resignation, Congress passed the resolution:

That Congress entertains a high opinion of the ability, integrity and past services of Dr. William Brown, Physician-General; but as circumstances will no longer permit his continuance in the service, his resignation is accepted.

In resigning, he forfeited his right to pay in bounty lands; but so highly were his services esteemed that the general assembly of Virginia made an exception in his case and decreed that he should receive the pay due him, and also that he should be entitled to the bounty of land allowed surgeons of regiments raised under the authority of the state (Hennings Statutes, Vol. VI).

Dr. Brown married Miss Catherine Scott of Alexandria, Va., and had a large family. His son, Gustavus Alexander, became a physician and practiced in Alexandria, Va., many years.

Dr. Brown died, Jan. 13, 1792, and was buried at Preston, an estate near Alexandria, Va.

1135 West Franklin Street.

MEDICAL AID IN RURAL DISTRICTS

Inaccessibility of medical and nursing aid, according to studies of maternity care in six rural areas of four states made by the Children's Bureau of the U. S. Department of Labor, is responsible for much suffering and even death. In a northwestern county and in a southeastern county there were nearly twice as many persons per physician as the average for the United States; in a southern mountain county there were four times as many. A vast area in the far Northwest, larger than Connecticut, was served by three registered doctors. Moreover, most of the doctors in every rural county were located at the county seat, while the remoter parts of the county were entirely without medical service. More than one third of the families in the far northwestern county studied were 20 miles or more from the nearest doctor, ten being from 50 to 100 miles away. In a southern county more than one fourth of the families were 10 miles or more from a doctor, and in another county 25 miles was not an uncommon distance.

Actual miles were not the sole obstacle to obtaining medical help at confinement. Rough roads, crossed by rivers; slippery mountain trails, almost impassable at best, become totally so under bad weather conditions. As a result, doctors arrive from several minutes to twenty-four hours too late to deliver their patients. Many families, discouraged by repeated failures to get a doctor in time, are tempted to do without one altogether; to others the thought of a doctor does not occur unless the patient's condition becomes critical. In a southern county only sixty-eight out of 160 mothers had a doctor at their last confinement; in only eight out of sixty-six confinement cases in a northern county was a physician secured; and in still another more than two thirds of the women did not have a physician when their babies were born. Three were entirely alone, and forty-six had only their husbands in attendance. Women would in many cases leave home for confinement if hospitals were within reach. But one 5,500 mile area had no hospital; neither had the southern mountain county. Reaching a hospital meant a journey of several days by wagon trail, or one by stage across the roughest of mountain roads. In a large number of cases the mother has no nursing care, except that given by an untrained hired girl, a relative, or a neighbor. Figures gathered from five rural counties are small in number but appalling in significance: 45 out of 89 babies who died during their first year; 22 out of 28; 12 out of 15; 10 out of 16; 10 out of 14, died before they were one month old. These figures are further corroborated by the Bureau of the Census which gives the increase in mortality rates from premature birth and injuries at birth. The first has increased from 17.5 per thousand of the population under 1 year of age in 1910 to 21.1 in 1917, and the other from 3.2 in 1910 to 4.6 in 1917. These excessive

rates are due to the condition of the mother and indicate plainly that motherhood is not receiving the protection it needs. As the census report itself says: these increases "should serve as food for thought."

Medicolegal

Unskilful Treatment of Injuries—Cross-Examination

(*Smith v. Missouri, K. & T. Ry. Co. (Okla.)*, 185 Pac. R. 70)

The Supreme Court of Oklahoma, in reversing a judgment rendered in favor of the defendant railroad company, in this personal injury case, holds that, when a party has used reasonable care in selecting a physician or surgeon, but owing to unskilful treatment the injury has been increased, the party causing the original injury will be held liable for damages for the latter; and the issue is not whether the physician or surgeon was, in fact, a man of high skill, but whether he bore such reputation as would justify the plaintiff in calling for his services under the obligation to exercise good faith in the choice of his physician. The court says that it might be conceded that the plaintiff was not well served by the physicians first called to attend him, and those who treated him for the first year following the accident, as he was suffering from a broken bone in the arm and a dislocated joint, and these physicians did not discover the extent of his injuries. However, the plaintiff was not at fault on this account. All of these physicians were regularly licensed physicians and surgeons, and his good faith in calling them was not questioned. The trial court properly instructed the jury to the effect that it was incumbent on the plaintiff to make use of reasonable means to effect as speedy and complete a recovery as could reasonably be accomplished, and for that purpose he was required to use reasonable care in the selection of competent and skilful surgeons and physicians, and that, if he failed in this respect, he could not recover damages for an aggravation of his injury or result therefrom, occasioned by such failure. The plaintiff offered proof to the effect that the three physicians he called bore the reputation in that community as being skilful and competent physicians and surgeons. That evidence was objected to by the defendant, and the objection was sustained. It was error to exclude that evidence. It was competent for the plaintiff to show that he acted in good faith and used due care, by employing well-known and reputable physicians to treat his injury.

Finally, the plaintiff called another physician, on whose advice he was sent to Oklahoma City, where a roentgenogram of his arm was taken, which disclosed a broken bone and a dislocated joint, after which he employed two or three specialists to treat the arm. When these specialists were called at the trial to testify in behalf of the plaintiff as to the character of his injury and its probable duration, the defendant, on the cross-examination of these witnesses, was permitted, over the objection of the plaintiff, to attempt to show that the treatment he received from the physicians first called by him was not the proper treatment, and this character of cross-examination was carried to such an extent as to introduce a collateral issue into the case, one not raised by the pleadings, and the issue on trial, namely, the liability of the railway company for the plaintiff's injuries, was lost sight of, and the trial permitted to develop into a trial of the physicians. By reason of this irregular conduct of the trial, the real issue before the court and jury was so obscured that the collateral issue was the only one really tried by the jury, and on which the verdict was returned for the railway company. This character of cross-examination was not permissible for two reasons: (1) Because it was irrelevant, and tended to support an issue not raised by the pleadings and not submitted to the jury for determination. (2) Because it extended beyond the direct examination of the witnesses. An attorney has no right to cross-examine a witness, except as to the facts and circumstances connected with the matter stated in his direct examination. If he wishes to

examine him on other matters, he must do so by making the witness his own, and calling him as such in the subsequent progress of the case. It was no answer to this assignment of error to say that this line of cross-examination was permissible to determine the competency of the expert witnesses, and to test their knowledge and skill, and that its tendency was merely to reduce the amount of the plaintiff's recovery; and since he did not recover anything by the verdict of the jury, the error, if any, was harmless. From an examination of the entire record the court is of the opinion that the improper cross-examination probably resulted in a miscarriage of justice, and was sufficient grounds for awarding a new trial.

Injured Employee Treating Himself

(*Banner Coffee Company et al. v. Industrial Commission et al. (Wis.)*, 174 N. W. R. 544)

The Supreme Court of Wisconsin, in affirming an award of the industrial commission of \$3,000 damages in favor of the widow of a teamster employed by the company, says that on February 19 he was kicked by a horse over the shin of his left leg. The injury did not appear to be serious, and he continued in the performance of his usual duties until the 27th. In the meantime he applied carbolic salve, and bandaged the injury with a cloth. During the afternoon of the 27th, he told a fellow workman that he could do no more: "everything is feeling numb; it is my back that shivers." He was told to go home and take care of himself. He went home, and on the same day the company was notified that he was in a serious condition. March 1, the company's physician called to see him. The physician found that he had a severely infected ulceration over the shin of his left leg, about the size of a dollar, with a temperature of 102.5. He had the man removed to a hospital, where he died, March 4, as a result of infection.

It was contended that the proximate cause of the man's death was his refusal to adopt such means as an ordinarily prudent person would use under like circumstances, the undisputed record showing, as it was contended, that the proximate cause of the infection was the failure to have immediate medical attention. But, while conceding that persons highly appreciative of the dangers resulting from infection would at once consult a physician, the court cannot say that this is true of the great mass of mankind under the same or similar circumstances. It is a matter of common knowledge that strong, healthy men engaged in manual labor frequently give such trifling injuries, which would arouse the apprehension of others, little thought; and in comparison with the number of such injuries, the instances followed by infection are not numerous. If they are treated at all, home remedies are applied, just as was done by this man. Carbolic salve was his remedy for cuts, bruises, etc., and this he applied. The injury itself was not sufficient to keep him from his work, and he went about performance of his daily duties, attaching little consequence to the injury. The court does not think it is customary for laboring men to rush to a physician every time they sustain a cut, bruise, or abrasion of the skin, and it cannot say as a matter of law that the conduct of this man was not that of the great mass of mankind under the same or similar circumstances.

Point was made of the fact that one of his fellow workmen, immediately after the kick, told him he had better see a physician. The district manager also testified that he saw him on the morning of February 20, and told him to go to a certain physician immediately; that he saw him a few days later, and asked him whether he had been to see a physician, and he said he had been treating himself, whereupon the district manager replied that he thought it would be best for him to go to a physician and have him examine him, and the man said he would. But, in the absence of any representation on the part of the company that it would be liable for the physician's fees, it could not be said that the man unreasonably refused to accept or receive medical services tendered to him by the company. What was said to him by his fellow laborer and the district manager amounted to nothing more than a suggestion on their part that he ought to see a physician. It goes without saying that their opinion in this respect

was no better than his. He was in a position to judge of the necessity of consulting a physician as well as they, and perhaps better. Furthermore, it was not at all plain from the record that, if he had consulted a physician, his life would have been saved.

Valid Provisions for the Quarantining of Persons with Venereal Diseases

(*Ex parte McGee et al. (Kan.)*, 185 Pac. R. 14)

The Supreme Court of Kansas, in denying the petitioners a writ of habeas corpus, holds that Chapter 205 of the Laws of 1917, which undertakes to protect the public health by preventing the dissemination of dangerous communicable diseases, through isolation and quarantine measures, is not unconstitutional on the ground that it delegates legislative power, because it confers on the state board of health authority to designate such diseases as are infectious, or communicable in their nature, and to prescribe proper control measures. The court says that the necessity for legislation of this character was demonstrated by very recent events. If, when this statute was before the legislature, it had designated all the infectious, contagious and communicable diseases it knew, and had prescribed regulations for their suppression and control, it would have omitted the deadly influenza which soon afterward made such appalling inroads on the lives and health of the people of the state. To meet emergencies of this character, it is indispensable to preservation of the public health that some administrative officer or board should be clothed with authority to make adequate rules which have the force of law.

Nor were rules of the state board of health, adopted and published pursuant to the statute, and provisions of a city ordinance framed in accordance with the rules of the state board of health, unreasonable because they authorized the isolation of men infected with venereal disease at an institution provided by the state for the isolation and treatment of such diseases. It was not long after its enactment until specific application of the statute to venereal diseases became urgent, on account of social conditions attending the concentration of large bodies of troops at the three United States military establishments in the state. The state board of health declared syphilis, gonococcus infection and chancroid to be infectious, contagious or communicable in their nature, and notifiable diseases dangerous to the public health, and made and published rules and regulations for the control and suppression of such diseases. The rules necessarily involved the isolation of diseased persons, and facilities for isolation where such persons were found in localities where such facilities were totally inadequate. Provision was made for the quarantine and medical treatment of women at the industrial farm for women. Provision was made for the isolation of men in one of the penitentiary buildings, for their treatment at the penitentiary hospital, and for certain liberties outside the walls of the institution in connection with a few hours' work each day on the penitentiary farm. The portions of the state property thus set apart for the use of men were designated the "Kansas State Quarantine Camp for Men, at Lansing," and the portion set apart for the use of women was designated the "Kansas State Quarantine Hospital for Women, at Lansing." Experience demonstrated that the men sent to the quarantine camp thus established were, generally speaking, a bad lot, and the board of administration provided that they should be subject to such rules for the discipline and control of the institution as the warden, with the approval of the board, might adopt. The isolation orders ought not to have used the term "state penitentiary," and should be amended by employing the official designation, the "State Quarantine Camp for Men, at Lansing."

The question of whether the petitioners were diseased was one of fact, determinable by practically infallible scientific methods. The city health officer was authorized to ascertain the fact. He certified to the existence of disease, and, in the absence of a charge of bad faith, or conduct equivalent to bad faith, on his part, his finding was conclusive. Reasonableness of provisions relating to discovery and to examination need not be determined here. It may be observed, how-

ever, that while provisions of the latter class cut deeply into private personal right, the subject is one respecting which a mincing policy is not to be tolerated. It affects the public health so intimately and so insidiously, that considerations of delicacy and privacy may not be permitted to thwart measures necessary to avert the public peril. Only those invasions of personal privacy are unlawful which are unreasonable, and reasonableness is always relative to the gravity of the occasion.

A person regularly ordered to be isolated at the state institution is not entitled to a writ of habeas corpus for his discharge because he is able to provide himself with proper treatment, at an isolated place in the locality of his residence. The public health authorities are not obliged to take chances.

True Object of Harrison Narcotic Law

(*United States v. Parsons (U. S.)*, 261 Fed. R. 223)

The United States District Court, District of Montana, says that the Harrison Narcotic Law is ostensibly a revenue measure, and within limits the courts must recognize it as such. At the same time, any one with sense enough to be at large without a keeper knows that the revenue feature, which possibly returns cents for dollars spent in administration, is only a fiction and device to enable Congress, otherwise disabled to suppress opium traffic and use, to hinder and obstruct such traffic so far as may be done incidentally to the exercise of revenue power. It is one of many like and regrettable devices to evade constitutional limitations, to impose duties of the states on the United States, and to vest the latter with nondelegated and reserved police power of the former. The limits are that, if in any such measure Congress incorporates arbitrary and unreasonable inhibitions, in that they are not calculated to promote the revenue features, but intended to promote some object not within congressional power, to that extent the statute is unconstitutional and void, and the courts are bound so to declare it. Section 2 must be construed to be in aid of the only object of the act that is constitutional, namely, to create and safeguard revenue. Nothing in Section 2 forbids purchases for any lawful use. Among such may be purchase to destroy, to absorb the supply, to prevent purchase by others, or to obstruct illegal traffic, all of which are lawful purposes, and none of which are within Section 2, even as purchase for personal use is not; and a demurrer is sustained to an indictment that charged purchase for personal use.

*Surgical Hazards in Diabetes. N. B. Foster, New York.—p. 382.

Gunshot Wounds of Chest.—In a series of gunshot wounds classified by Fowler and Mencken according to the anatomic region involved, wounds of the thorax (139) constituted 8.6 per cent. Of these 118 involved the chest wall. Twenty-one were intrathoracic wounds. There were no wounds of the heart seen. Penetrating wounds of the lung and pleura (twenty-one) composed 17 per cent. of gunshot wounds of the chest. Some of these cases are analyzed.

Results of Operation for Breast Tumor.—A little better than 62 per cent. of the patients operated on by Davis for breast cancer have been free of recurrence for from three to twenty years. To have a set form of incision Davis believes is a mistake. The location and extent should determine the line of incision and the amount of skin to be removed. If the growth is deeply seated, only a comparatively small amount of skin need be sacrificed. If near the surface, and especially if the skin is adherent, a much larger area should be removed. The most methodical part of the operation, as well as the more extensive, occurs beneath the skin. There is really no especial limitation to the amount of fascia and fat that may advantageously be sacrificed.

Diaphragmatic Hernia.—The contents of the hernia in Rigg's case consisted of the pyloric portion of the stomach, the greater portion of the transverse colon and almost the entire omentum. The hernia was of traumatic origin. The opening was to the right of the midline and was not through one of the normal openings in the diaphragm. The sac of the hernia was formed by the diaphragmatic peritoneum and the diaphragmatic pleura.

Congenital Diaphragmatic Hernia.—Frank's patient was 16 years old. He had a hernia of the stomach and duodenum into the right chest, almost half filling the right chest cavity. A successful operation was performed.

Technic of Appendectomy.—Soresi believes that the special points of the technic that he advises in all acute cases: ether-

rubber preparation of the skin; pararectus incision; freeing of only the external portion of the cecum; raising up the cecum, so as to expose the base of the appendix, immediately severing the appendix close to its base and inverting it; then following the distal portion of the appendix and removing as much of it as possible; paraffin gravity drainage when pus is present; closure of the abdominal wound in all cases; paraffin gravity drainage of the abdominal wall; elastic closure of the skin, and the application of an elastic belt as an external dressing, answer all the desiderata. Life is saved more often if this technic is followed. The technic recommended is said to be ideal for all cases, because it prevents the spreading of infection in all cases and does not lower the resistance of the peritoneal organs, and does positively drain out safely any secretions that should be drained out. It prevents the formation of fecal fistula, of dangerous post-operative adhesions, of postoperative hernia; it allows a maximum of comfort to the patient.

Operating on Diabetics.—The treatment of patients with diabetes mellitus as a preparation for surgical operation Foster says requires a departure in no respect from recognized principles. The object of this treatment is the restoration of normal metabolism and the measure of success is the blood sugar and carbon dioxide of the plasma. Foster gives sodium bicarbonate emulsified in olive oil subcutaneously, from 10 to 15 gm. of sodium bicarbonate in 10 c.c. of oil. Attention to a copious fluid intake and catharsis is important. Some patients with moderately advanced diabetes can, by treatment of this type, be carried through operative procedures, but not all. Some, especially those with virulent infections of the cellulitis type, do not respond to any method or procedure.

Archives of Dermatology and Syphilology, Chicago

April, 1920, 38, No. 4

Infection of Skin with *Endomyces Albicans*.—Tanner and Feuer report an investigation of a fungus that caused a series of lesions on the index finger of a woman. The fungus seems to be identical with *Endomyces albicans*.

Peculiar Fungus Infection of Skin (Soorpilze).—The condition present in Engman's case looked exactly like that of a *Tinea inguinalis* or that produced by *Epidermophyton inguinale*. The process was very rebellious to treatment. Preparations made with potassium hydroxide in the usual manner for looking for such organisms, disclosed a peculiar fungus. Prof. George Moore of the Missouri Botanical Gardens reported that the fungus belongs to the general group known as the hyphomycetes, or fungi imperfecti. This group is a sort of botanical wastebasket for those forms of which the life history is not completely known, and consequently it is not well defined. The plant belongs to the order Moniliales and resembles to some extent both *Monilia* and *Oidium*. There is the strongest probability, however, of its belonging to the genus *Botrytis*. As to the relation of the organism to other known pathogenic fungi, it comes closest to the well known 'Soorpilze' of thrush, which has received some ten or a dozen different names and the precise systematic position of which has never been satisfactorily worked out.

Necropsy Findings in Congenital Scleroderma and Sclerodactylia.—The diagnosis Weidman made in this case depends partly on the clinical features, but more on the morbid anatomic—essentially microscopic—findings. The disease

occurred immediately after birth, was associated with a bloody diarrhea and ended fatally. The only clinical feature, in fact, against the diagnosis of sclerema was the symmetry of the involvement. The hide-binding in this 15 day old baby, probably syphilitic, dying with enteritis and meningitis, suggests sclerema neonatorum; but it is symmetrical and periarticular, and at necropsy the induration is found to be purely subcutaneous. On these and other grounds, the diagnosis of sclerema neonatorum is rejected, and the case finally placed in the general group of scleroderma without affixing any new name to this pure subcutaneous form, believing it to be of the same known nervous causation as many other cases of scleroderma.

Congenital Ectodermal Defect.—Goeckermann's patient was a woman, 21 years of age. The case was typical of this group and presented no unusual features. The patients in this group all present a facies very closely resembling that of heredosyphilis. The influence of syphilis in the production of these congenital defects is probably nil. The reported cases of this group of ectodermal defects have exhibited a total absence of sweat glands, an almost total absence of sebaceous glands, a hypotrichosis with absence of lanugo hair, and a dental aplasia. Such patients suffer from a disturbance of the heat regulating mechanism, dependent on the inability of their skins to eliminate the necessary amount of water to keep the temperature level constant under varying external conditions.

Saturation in Roentgen Therapy.—An attempt is made by Kingery to establish an analogy between biochemical mass reactions and the changes produced in tissues by absorption of the roentgen rays.

Treatment of Chancroid with High Frequency Vacuum Electrode and Copper Sulphate Solution.—Jacob's paper is based on a study of fifty-two cases. Of these, four developed buboes, two of which resolved and two suppurated. Thirty-nine healed within two weeks, seven in three weeks, and six in from three to five weeks. No ulcer showed any tendency to spread after treatment. The cases detailed may well be compared with sixty-three cases of chancroids treated according to older methods, including treatment with: argyrol, calomel, black wash, dusting powder, phenol, iodine, iodoform, etc. Twenty-eight of these developed buboes, and had come under observation six months before. The reason for not having a larger percentage of early cures, Jacob thinks, is undoubtedly due to irregularity of attendance on the part of the patient. The method of treatment used was that first described by Robbins and Seabury in *THE JOURNAL*, Oct. 13, 1917, p. 1217.

Acquired Circumscribed Hyperhidrosis.—Pusey describes the case of a girl, aged 22, who had a sweating area on the extensor surface of the wrist and on the back of the hand toward the ulnar side, from 2½ to 3 inches wide and 5 inches long. It was sharply defined and its location did not vary. The skin was slightly pinkish and sodden. Sensation in it was diminished, but it was otherwise normal. The sweating occurred in almost constantly repeated attacks. By applying a 25 per cent. solution of aluminum chlorid cautiously over the affected area, the sweating was checked in the course of a week or ten days, and there has been no unusual sweating of this area for two months.

Study of Brain Repair.—The method of brain repair following the production of an injury to the brain with the hot needle stab was studied by the Macklins for as long a period as seventy-four days after the trauma. A uniform technic of staining was carried out, each animal receiving intracranially 4 or 5 c.c. of a 1 per cent. aqueous solution of

Grübler's trypan blue forty-eight hours before being sacrificed, followed by a second dose after twenty-four hours. In those animals which were killed sooner than forty-eight hours after the operation, the same procedure was carried out, the dye being given at the proper intervals before the operation. The findings are set forth in detail. The illustrations accompanying this report are very well made and elucidating.

Epidermoid Papillary Cystoma Involving Third Ventricle.

—In the case reported by MacPherson, the growth did not show the large polygonal cells with densely staining protoplasm, characteristic of tumors of the pars intermedia, nor did it resemble those arising from the choroid plexus. The infundibulum was distended, and its tissue partially replaced by the tumor with a suggestion of a tumor stalk near the right ventrolateral surface. Cross sections through the third ventricle and pituitary body, which was removed intact still attached to the brain, showed the duralike capsule of the growth to be continuous with the connective tissue of the gland. The pituitary gland was normal. The squamous epithelium of the tumor showed a suggestion of intercellular spines and well marked scaling; but no hair or sebaceous material was found. Vacuolization and cilia formation are not differential, and there does not seem to be any adequate criterion by which one may judge how this epidermoid tissue happened to be in this location. From the situation and character of the growth, it probably originated as a result of a developmental abnormality of the infundibulum or from a hypophysial "rest." In the grouping of the third ventricle tumors according to the symptomatology, suggested by Weisenburg in an excellent review of thirty cases, this case would be in Class 1. Though the aqueduct was not dilated, the posterior part of the ventricle and the periaqueductal structures were apparently involved indirectly as shown by the pupillary disturbance without, however, paralysis of associated ocular movements and a reeling gate suggestive of involvement of the red nuclei or superior cerebellar peduncles. The patient's tendency to drag his feet and the weakness of the legs might be interpreted either as evidence of pressure on the internal capsules or of cortical injury. One of the early symptoms in this case was the evidence of hypopituitarism. Another striking feature was the drowsy, somnolent, apathetic condition of more than one year's duration, with periods approaching normality. There was an internal hydrocephalus with increased intracranial pressure, cerebral anemia, edema and pituitary disturbance. The patient was 52 years old, and had been ill for sixteen years. The clinical diagnosis was cardiorenal psychosis. A complete report of the necropsy is given.

Brain Tumors as Seen in Hospitals for the Insane.—It is not a rare experience for the pathologist in a hospital for the insane to find at necropsy a brain tumor undiagnosed during life. Morse made an inquiry into the reasons for the lack of diagnosis, and whether the group of brain tumor cases in hospitals for the insane presents any special characteristics as to symptomatology, age or stage of disease on admission, which would distinguish them from cases in general hospitals. The histories and necropsy protocols of forty-six cases were studied, and in most instances were examined in frontal sections. In about one half of the cases the brains and cords were also studied histologically.

Streptococci in Milk.—To establish the possible types of streptococci which may appear in market milk, examinations of the vaginal discharges, saliva, feces and skin of cows in a large herd were undertaken by Jones. He found that the principal source of streptococci in milk is the cow's udder. The udder streptococci fall into two broad groups; those of the larger group agree in cultural characters and agglutination affinities with mastitis streptococci; the smaller group is composed of low acid producing streptococci. All the streptococci from the vagina, saliva, skin and feces have been non-hemolytic. Those from the saliva form a heterogeneous aggregation in which individuals fermenting raffinose, inulin and mannite predominate. From the skin a characteristic streptococcus has been found. It produces acid in dextrose, lactose, saccharose, maltose, raffinose, mannite and salicin, but fails to acidulate medium containing inulin. The fecal streptococci are characterized by the formation of large amounts of acid in dextrose, lactose, saccharose, maltose, raffinose, inulin and salicin. Mannite is not fermented. Neither the fecal nor the skin streptococci have been isolated from the bottled milk with any great frequency.

Experimental Diabetes.—The basis of these studies by Allen has been a form of diabetes produced by removal of the greater part of the pancreas of animals, leaving a remnant about the duct secreting normally into the duodenum, thus avoiding the rapidly fatal cachexia of total pancreatectomy and also the pancreatic sclerosis and deficient digestion of Sandmeyer diabetes and affording a very close and satisfactory reproduction of the clinical disorder. The observations support the conclusion that partially depancreatized animals show no inherent increase of tendency to diabetes.

Carbohydrate Diet in Diabetes.—The injurious effects of excessive carbohydrate diet were demonstrable by Allen in partially depancreatized dogs, in the same manner as in human patients. With severe diabetes there is rapid progress of emaciation and weakness and early death. With milder diabetes, there is frequently a transitional state following operation, when the fate depends on the diet. If the tolerance is spared for a time, recovery sometimes occurs to such extent that diabetes cannot be produced by any kind or quantity of feeding, but only by removal of a small additional fragment of pancreatic tissue. The proper degree of carbohydrate overfeeding is important in this early period for producing the most useful type of diabetic animals; namely, those having good digestion and general health combined with a permanent lowering of assimilative power, like the condition of human patients. In the early stage, glucose is more powerful than starch in producing diabetes, and animals which are progressing toward complete recovery on starch diet can be sent into hopeless diabetes by admixture of glucose. The difference seems to be merely of the rate of absorption, and indicates that a rapid flood of carbohydrate is more injurious to the pancreatic function than a slow absorption. Whenever permanent diabetes is present, so that complete recovery is impossible, starch brings on glycosuria more slowly than sugar, but just as surely. The difference in time in different cases amounts to days, weeks or months. The clinical lesson from such experiments is that even if a patient becomes free from glycosuria on withdrawal of sugar only, nevertheless other foods should also be limited. No significant differences were observed by Allen between the assimilation of different starches, or any extreme lowering of the carbohydrate tolerance by proteins, such as alleged

by certain writers in connection with the "oatmeal cure." Repair of traumatic inflammation and hypertrophy of the pancreas remnant are mentioned incidentally as the basis of the early tendency to recovery, and also hydropic degeneration of Langerhans' islands as an accompaniment of the lowering of tolerance by excessive diet. These are believed to have their parallels in human cases, and are to be described more fully hereafter.

Experimental Pneumonia.—The method of inoculation used by Blake and Cecil was by direct intratracheal injection under aseptic precautions, by the insertion of a small caliber, dry, sterile needle into the lumen of the trachea between the tracheal cartilages just below the larynx and the introduction of the culture by means of a Luer glass syringe inserted into the stock of the needle. Thirty-seven normal monkeys were injected. In thirty-two instances lobar pneumonia in all its aspects resembling the disease as seen in man was successfully produced. In five cases the monkeys failed to develop pneumonia. In one instance lobar pneumonia was produced by experimental contact infection. Normal monkeys inoculated in the nose and throat with large amounts of pneumococcus culture have failed to develop lobar pneumonia though carrying the organism in their mouths for at least a month. They have likewise failed to show any evidence of upper respiratory tract infection. Monkeys inoculated subcutaneously or intravenously with pneumococcus culture have in no instance developed pneumonia, but have either died of pneumococcus septicemia or recovered without localization of the infection in the lungs. These observations lead the authors to conclude that the pneumococcus is the specific cause of lobar pneumonia. The pneumococcus is unable to initiate an infection of the normal mucous membranes of the upper respiratory tract or to produce pneumonia following intravenous injection, but must gain access to the lower respiratory tract by way of the trachea in order to cause pneumonia. Lobar pneumonia is, therefore, bronchiogenic in origin. Invasion of the blood stream by the pneumococcus in lobar pneumonia is secondary to infection of the lungs. The character of the leukocyte reaction during the course of lobar pneumonia bears a fairly definite relation to the course of the disease.

Pathology of Pneumococcus Pneumonia.—In this paper the authors describe the pathology of pneumococcus pneumonia experimentally produced in monkeys, in order to show that the disease is identical with lobar pneumonia in man, and, they present observations concerning the pathogenesis of lobar pneumonia based on study of the pathology of lobar pneumonia in monkeys. In lobar pneumonia the pneumococcus primarily invades the lung tissue at some point or points near the root of the lobe. The pneumococcus subsequently spreads throughout the lobe by way of the interstitial framework and lymphatic system. Lobar pneumonia, therefore, is primarily an interstitial infection of the lung. Consolidation in lobar pneumonia begins in the alveolar tissue proximal to the hilum and progressively spreads to the more distal tissue until complete lobar consolidation develops.

Experimental Syphilis.—A study was made by Brown and Pearce of the infections produced in rabbits inoculated in the testicles with two strains of *Spirochaeta pallida* which had been carried in rabbits for several years. Infection resulted in all instances; the incubation period varied, as a rule, between two and three weeks and under properly chosen conditions could be reduced to approximately three weeks or less. The resulting infection pursued a typically cyclic or relapsing course which affected both the spirochetes and the associated lesions in the testicle. The specific reaction in the testicle showed considerable variation in the speed and sharpness with which successive phenomena occurred as well as in the character and extent of the processes themselves. These reactions were of two fundamental types. In one group of animals, the reaction was characterized by an intense cycle of acute exudation and infiltration with a lesser degree of proliferation, followed by crisis and subsequent recurrence of secondary cycles of proliferative reaction of a minor degree. In the other group of animals, the reaction was more chronic in character and consisted largely of infiltration and

proliferation. The progress of the reaction was more gradual, and sharp alterations in its course were absent. The infection progressed by a succession of stages with slight and irregular remissions. In a third group of animals, the reaction was subacute, combining at the same time the processes of exudation, infiltration, and proliferation. The first cycle of reaction was fairly acute and terminated in a definite crisis with moderate regression which in turn was followed by recurrence and more or less pronounced secondary cycles of proliferation. In all cases of outspoken infection, there was diffuse involvement of testicle, tunic, epididymis, and cord, but as the infection progressed, the lesions underwent many transformations, so that a variety of lesions was formed from processes which in the beginning were of a common type. Eventually, the reaction became more irregular and the infection became centered in one or more foci which were commonly situated in the epididymis, tunics, scrotum, or mediastinum testis. These centers served as residual foci of infection.

Result in Case of Myxedema After Twenty-Nine Years.—When Murray first exhibited this patient in 1891, she was 46 years of age. She had then been ill for about five years. The condition was a typical myxedema. The patient was given thyroid extract prepared from a sheep's thyroid. A hypodermic injection of 25 minims of the extract was given twice a week at first, and later on at longer intervals. When the oral administration had been shown to be equally efficient, she took 10 minims by the mouth six nights a week, so that 1 dram was consumed in the course of each week. On this dose she remained in good health, and free from the signs of myxedema. She continued to take liquid thyroid extract regularly until early in 1918, when it became difficult to obtain, so that she was given dry thyroid extract in a tablet instead. She enjoyed excellent health until early in 1919, when she developed edema of the legs, and died in May, 1919, at the age of 74 from cardiac failure. This patient was thus enabled, by the regular and continued use of thyroid extract, to live in good health for over twenty-eight years after she had reached an advanced stage of myxedema. During this period she consumed over 9 pints of liquid thyroid extract or its equivalent, prepared from the thyroid glands of more than 870 sheep.

Antistreptococcus Serum in Quinsy.—On the assumption that the primary cause of quinsy was a streptococcus, Forsyth determined to treat all cases of quinsy with antistreptococcal serum. Cases were selected in which the abscess had not perforated and in which the conditions were definitely acute. The following routine was adopted: Serum (10 c.c.) was injected at once; if there was any doubt of diphtheria 2,000 units of antidiphtherial serum were added. Ten cases only were treated. The most definite result obtained in these cases was the relief of pain in from six to twelve hours; the more or less acute pain when swallowing was eased some hours after that, but within a definite time before the abscess ruptured. In no case was incision of the abscess required by reason of the severity of the symptoms, and in all so treated there was pus discharging from the abscess on the fourth day of the illness. The temperature approximated to the normal one or two days after the serum injection.

Carcinoma of Thyroid.—One unusual feature in Hughes' case was the age of the patient, 13 years. The whole gland and the involved lymph nodes were removed. Three months after operation there was no sign of any recurrence and the patient was perfectly well.

Surgical Treatment of Chronic Ulcers of Stomach and Duodenum.—Sherren maintains that the result of the operative treatment of chronic duodenal ulcer rivals that of any other major operation. With care during operation and with the after-treatment jejunal ulcer should become almost, if not quite, unknown. Gastrojejunostomy is the operation of choice in all except those in which the ulcer is involving the stomach or deeply eroding the pancreas. Both should be treated by excision. Among his cases "not quite well" are three in whom this latter condition was present. Sherren's successes more than two years after operation are a little over 80 per cent. of those operated on. This is considering all who cannot be traced or who died before the two-year period of other causes, thirty-two, as failures. The successes among those traced are over 90 per cent. Among 310 cases of chronic gastric ulcer in which operation was performed the mortality was 11. These figures include all ulcers treated by operation, except for acute perforation. All the partial gastrectomies except two are quite well, and none complain of any discomfort from the smallness of the stomach. I have been able to trace twenty-two patients treated by excision combined with gastrojejunostomy; all except two are quite well. Of the 219 survivors of those treated by gastrojejunostomy alone, of whom Sherren has been able to keep 187 under observation for over two years; 162 have remained perfectly well. To summarize the results: Of the 310 cases, 220 have remained perfectly well for more than two years or died at a later date of other causes after having had no further gastric trouble. This is 75 per cent. of those operated on. Sherren emphasizes that while gastrojejunostomy combined with general abdominal exploration and dealing with other diseased organs is curative in the majority of cases of chronic duodenal ulcer, each must be studied and those eroding the pancreas or spreading to the stomach removed. Gastric ulcers which have perforated and are adherent to neighboring organs, indurated ulcers on the lesser curvature, and all in which there is any suspicion of malignancy must be treated by partial gastrectomy. He believes that gastrojejunostomy for chronic gastric ulcer will become the less frequent operation. Symptoms arising later if the correct operative procedure has been adopted are due to mechanical or ulcerative changes in the region of the anastomosis, both prevented by careful technic in the majority of cases, and becoming less frequent as individual experience ripens.

Arneth's Reaction in Pulmonary Tuberculosis.—A series of thirty cases representative of various stages of pulmonary tuberculosis were examined by Treadgold; all had tubercle bacilli present in the sputum. All cases were examined on at least three occasions over a minimum period of two months. The average time each case remained under investigation was 3.8 months, and the average examinations made were 4.15 per case, a total of 124 blood films being counted. Analysis of these cases showed that twenty-nine had a more or less marked shift to the left, and one a definite and continuous shift to the right. There were ten deaths, ten cases discharged unimproved after treatment, and ten cases definitely improved. Although these figures bear out, to some extent, claims made by other observers that the more marked the left shift the worse the prognosis, it also reveals the great danger of drawing any conclusions from single Arneth examinations. Again, two consecutive examinations showing a marked rise in the Arneth count are not necessarily indicative of the improvement in the lung condition of the patient. In view of the fact that the average tuberculous sputum usually contains considerable numbers of well preserved neutrophil leukocytes, films of tuberculous sputums were stained by Unna's polychrome-blue method, and the results contrasted with blood films of the same patients taken the preceding day. The first ten cases examined proved remarkably constant, the maximum variation in the count between the sputum and blood films being in no case more than 5 per cent. Further investigation showed, however, that the leukocytes of many perfectly fresh tuberculous sputums were disintegrated and impossible to count and the method was abandoned. On the whole, Treadgold's observations showed that a shift to the left is usually present

in cases of active pulmonary tuberculosis, the degree of shift being most marked, and generally progressive, in dying cases. It is less marked and is apt to remain fairly constant in cases which do not improve under treatment, while cases definitely improving usually show the least degree of shift, and this becomes progressively less as improvement continues. A constant and marked left shift in early suspected cases of pulmonary tuberculosis, where other sources of infection can be excluded, is presumptive evidence of active mischief. A left shift under 200 in old cases of "clinical arrest" is suggestive of recurrence and calls for minute and careful reexamination. Treadgold also reports on animal experiments.

Throat Antisepsis in Diphtheria.—A clinical study of fifty consecutive vaccine treated cases by Brownlie shows that local antiseptic throat applications are unreliable cures for the carrier and the positive throat. Diphtheria vaccine produces well defined degeneracy in morphological appearance of the cultured organism, followed by its complete dispersal from the locality invaded. In the past the diphtheria carrier has been subjected to hospital residence for weeks, perhaps months, which were avoidable. Diphtheria vaccine is effective in the treatment of the positive throat of diphtheria convalescents, and its use is administratively and economically sound.

Bone Condition Analogous to Rickets.—Brade-Birk's patient was breast fed. At the seventeenth week, when the child weighed 10 pounds 7 ounces, symptoms analogous to those of rickets were observed. The term "analogous to rickets" is used to prevent controversy as to terms. There seems to be a current belief that typical rickets cannot occur in a child so young; however, the signs in this case were typical.

Familial Ichthyosis Hystrix.—In Davies' cases the father's brother married the mother's sister. History of tuberculosis on father's side. No history of skin trouble or of illness of importance on either side. The mother's sister has four children, two of whom have typical ichthyosis. The mother describes the condition of her two boys at birth as follows: "They were born with their hands and their feet covered with a film, as if whitewashed." The white films refused to be washed off, but later, when the superficial layers had loosened, the underlying skin was rough and dry. When about 1 year old warts were first noticed on hands and feet, and these gradually spread and increased over rest of body. The other two children, who are unaffected, have been sleeping with them, and using the same towel. The mother has paid great attention to washing the boys. The two brothers are aged 12 years and 9 years, respectively. The skin of the face is dry and scaled, but clear of warts. Above the collar is a definite ring of grayish warts. The rest of the skin of the body is dry and scaly, and superimposed are numerous warts, varying in number in different localities. In the neighborhood of the joints, dorsal surface, and palms of hands and axillae the warts are especially numerous, and so closely packed that no normal skin can be seen. The penis also of the younger boy is covered with warts. The warts are grayish in color, and measure about 2 to 3 mm.

Gastric Myoma: Partial Gastrectomy. H. Bouquet.—p. 425.
 *Changes in the Rectal Mucosa Following Intrarectal Ether Narcosis.
 R. Savignac and J. Vidal.—p. 428.

Insufficiency of the Pylorus.—Bonorino recalls the fact that the organic and functional processes induced by true pyloric incontinence are not well known, though quite worthy of attention. He reports what he regards as a pure type of the anomaly in a syphilitic man of 36 with gastroduodenal ulcer and symptoms from the digestive tract for about three years. They included long periods of constipation followed by similar periods of diarrhea, but the stools contained no mucus or visible blood. Improvement in the general condition followed specific treatment, but symptomatic and dietetic measures were long required to abolish the symptoms of the ulcer and the occult blood in the stools. The exceptional feature of the case was the permanent gaping condition of the pylorus which in the roentgen picture behaved like a simple open tube draining the stomach, an absolute and permanent insufficiency of the pylorus. This insufficiency was probably due to adhesions around the pylorus holding it open. The lower margin of the stomach and the antrum seemed to be somewhat less movable than normal. The roentgen ray disclosed that when the opaque mixture reached the pylorus it passed on into the duodenum continuously without any contractions of the walls being observable. Surgical intervention was recommended, but the patient refused and left the service. Other conditions entailing insufficiency of the pylorus are reviewed in connection with this case.

Cancer of the Duodenojejunal Flexure.—Cade and Devic report a case of duodenojejunal cancer in a woman of 72 which presented some peculiar points of interest. Eighteen months before the patient entered the service of Cade she noticed that she was losing weight and that her strength was failing. Not until a year later did the first gastric symptoms appear. Then the patient began to be awakened occasionally nights by a moderate epigastric pain that was accompanied by a feeling of intense hunger. One month before entering the hospital she was suffering from vomiting spells and pain. The material vomited contained much bile, and the stomach was dilated. Peristaltic waves of rare intensity were observable. In view of the precarious condition of the patient, the certain indications of stenosis, and the fact that liquid nourishment could not be borne, an immediate gastro-enterostomy was done, which, however, resulted fatally thirty-six hours after the operation. The writers recall that Pic emphasized that gastric dilatation, accompanied by bile in the vomitus, was distinctly characteristic of duodenal cancer located below the papilla of Vater, as was shown at necropsy to be the case here. The feeling of intense hunger at night is accepted as a sign of duodenal ulcer, but here it was a sign accompanying cancer. It would seem that stenoses below the papilla of Vater are announced by two quite different series of signs, the one series being of a gastric order (duodenal reflux, vomiting, dilatation) and the other intestinal (constipation and at times even phenomena of occlusion). The first series is the more common.

Changes in the Rectal Mucosa Following Intrarectal Ether Anesthesia.—Savignac and Vidal state that as the result of rectoscopic studies on a series of cases, they were able to conclude that, while intrarectal etherization by the Monod method, slightly varied, and which they describe in detail, caused a light, acute, transitory rectitis, the inflammation was only superficial and produced no important subjective symptoms. About the only trouble was a slight tendency to constipation for a few days following the narcosis.

*Amyotonia Congenita. P. Haushalter.—p. 133.
 Inherited Syphilis and Dystrophies. V. Iturinel and H. Stévenin.
 —p. 145. Cont'n.
 *Purpura in Young Infant. T. Reh (Geneva).—p. 179.

Amyotonia Congenita: Oppenheim's Disease.—Haushalter reports three more cases of Oppenheim's disease to be added to the list of 155 cases collected by Comby. In Case 1 he emphasizes that the infant's respiration was almost

entirely diaphragmatic owing to the atony of the inspiratory muscles; also that the mother while pregnant with this, her eighth child, rarely noted any movements of the fetus, and they were unusually slight. In Case 2 the significant feature was that while the child, up to the age of 4, had remained flabby and inert, keeping whatever position he was placed in, he then underwent a rapid transformation. He gradually learned to walk, to carry things to his mouth, to get up from the floor, and even to dress himself. At 5 he could only say "papa" and "mama," but then he rapidly learned to talk; at 7 he started school; could write at 8, and at 11 he was in classes with boys of his age and did not seem to be their inferior mentally. His height was then 1.25 meters; weight, 20.5 kg. There was no disturbance of circulatory, respiratory, digestive or urinary functions. His body was well proportioned. There was, however, a diffuse, generalized, muscular atrophy, in spite of which he could walk and run like other boys, without becoming overfatigued. Owing to the suppleness of his joints he could execute many tricks of contortionists. In Case 3 the congenital amyotonia, predominating in the lower extremities, accompanied by diffuse muscular atrophy, continued to progress until death at 12 from bronchopneumonia. The habitual posture assumed by the child, together with the looseness of the joints and the muscular atrophy, had finally brought about a strange, doubled-up condition of the body, the left side of the thorax resting on the anterior wall of the abdomen, the left hip joint on a level with the axilla, with excessive scoliosis similar to that sometimes seen in myopathies. While the lesions resembled those of a myopathy, this case could not be classed among myopathy cases owing to the fact that it was congenital.

Purpura in Infant.—The infant had an erosion in its mouth soon after birth and the pneumococcus gained access to the blood stream and induced symmetrical purpura and terminal pneumonia.

 *Spasm of the Esophagus. J. Guisez.—p. 147.
 The French Navy in the Protection of France Against Disease. H. Chevalier.—p. 149.

Intra-Uterine "Drowning" of the Fetus.—Balthazard and Piédelièvre declare that the possibility of intra-uterine movements of the fetal chest, similar to respiratory movements, is now accepted generally by obstetricians and medicolegal authorities. These movements may draw in fluid, and the fetus may actually "drown" in consequence. This may occur with otherwise normal childbirths, and it may cause suspicion of infanticide. The only way to determine whether the drowning occurred in the uterus is to examine sections of the deep lung, as, under normal conditions, débris of the amniotic fluid are often found in the more accessible parts of the lung, although only in small amounts. Reuter's technic shows fetal epidermic cells in the amniotic fluid and the crystals of cholesterol from the meconium. When these are found in histologic sections of the lungs, there can be no doubt that the fluids were drawn deep into the lungs by the premature movements of the respiratory muscles. Still other elements of these fluids can be detected by the technic described.

Spasm of the Esophagus.—Guisez relates that he has examined with the esophagoscope 420 cases of primary spasm of the esophagus. Most of them were grave and permanent, but all were a local pathologic condition and usually yielded to local measures. His experience has demonstrated, he says, that the esophagus is an actual organ, with an active function in passing the food along. If the food is swallowed in chunks, the chunks are arrested at the narrower points and drinking, to wash them along, aids in the demands made on the esophagus wall, which responds after many repetitions with a permanent contracture. The primal cause, therefore, is defective mastication and only when this is corrected can the cure be permanent. As a rule, the subjects with spasm

of the esophagus are nervous or inclined to hysteria, but even when there is a tendency to nervousness, the lack of proper mastication is the primal factor.

Treatment of Alcohol Addiction. D. Jaguaribe and F. Regnault.—p. 266.

Acute Cervical Arthritis Following Scarlet Fever.—Mayet and Laval state that the cervical vertebrae are a frequent point of attack for scarlet fever arthritis. Not only rheumatoid pains of short duration arise in this region, but genuine arthritis as well, which sometimes takes on a peculiar character. During the acute period the arthritis is characterized by pain and by a certain amount of swelling, sometimes taking the form of severe wryneck with extremely violent pain when any attempt is made to move the head. In some cases ankylosis results which may require orthopedic treatment by means of head and neck plaster casts (Minerva casts) applied under general anesthesia. They report a case of acute cervical arthritis, after mild scarlet fever, in which there was suppuration and intense but transient torticollis; it subsided after evacuation of the abscess under general anesthesia. The pus was found back of the deep vertebral aponeurosis and prevertebral muscles, having worked in between the elements of the anterior common ligament, in front of the axis and third cervical vertebra. By the twenty-fifth day the cure was complete, the movements of the neck normal.

*Abscess in Lung. J. Chalié.—p. 249.
Beyrouth and Its Medical School. G. Gayet.—p. 284.

Abscess in the Lung.—The case reported by Chalié teaches that even with negative roentgen-ray findings, if the symptoms indicate a suppurative process in the lung, we should not hesitate to puncture. He introduced the needle at the point of least resonance and found pus at a depth of 6 cm. There was not more than 30 c.c. of pus, but prompt improvement followed its evacuation with speedy complete recovery. The general symptoms had dominated the clinical picture, progressive emaciation, with hollow eyes and extreme weakness, actual cachexia in a month's time, while the cough suggested acute tuberculosis. The abscess had developed after influenza with congestion of the base of the right lung.

*Diarrhea in Breast-Fed Infants. A. B. Marfan.—p. 1.
Medical Supervision of Wet-Nurses in the Provinces. P. Parisot.—p. 31.

*Skin Tuberculin Reaction in Children. Germaine Mioche.—p. 42.

Diarrhea in Breast-Fed Infants.—Marfan states that while diarrhea in breast-fed infants is frequent, in its primary form it is almost never associated with symptoms of infection or intoxication, at least not so as to present any serious or lasting symptoms. It has no profound effect on the nutrition, and is very rarely of a grave nature. He opposes the idea advanced by many that diarrhea in breast-fed infants frequently requires that the child should not be given the breast for a time; he thinks such indications are rare. Nor does he think that a change of nurse is often indicated. In the foregoing respects a radical distinction is to be made between breast-fed and bottle-fed infants, for the general nutrition and growth of the latter are quickly affected by diarrhea; hypothyrepsia and athrepsia often result; toxic

complications (cholera infantum) or secondary infections may arise requiring varied and rather complicated dietetic treatment. In breast-fed infants, if the diarrhea is light, the first day the intervals between feedings should be lengthened and the time at the breast should be shortened. The intervals may be lengthened to four hours and the time at the breast may be reduced to five or six minutes. During the intervals the infant should be given a few spoonfuls of pure boiled water. The second day the intervals are shortened somewhat; the third day the time at the breast may be slightly lengthened. Thus, by degrees, according to the effect secured, a gradual return to normal is brought about. But in severe cases three or four feedings are entirely suppressed and pure boiled water is substituted, a quantity about equal to the amount of milk usually taken by the child when well.

Skin Tuberculin Reaction in Children.—Mioche states that on the basis of experience gathered during five years in Marfan's service, the following conclusions may be drawn as to the clinical value of the tuberculin skin reaction: 1. It is the procedure of choice among the various diagnostic methods in which local reactions to tuberculin play a part. 2. Its diagnostic value is incontestable. 3. Starting with zero in the newly born, the number of positive cutaneous reactions increases progressively with the age of the subject. 4. In children under 1 year of age a positive reaction is a sure indication of progressing tuberculosis and usually of approaching death. In older children it is not a reliable index of tuberculosis in evolution unless supported by clinical evidence; and in adults its diagnostic value is practically zero. 5. As a method that will permit the examining physician to diagnose tuberculosis in infants it is incomparably better than all others, for by means of it he can recognize the presence of the disease at its very onset and thus perhaps be able to render some service.

*Fat Grafts. Mauclore.—p. 165.
Meat and Infant Feeding. G. Schreiber.—p. 169.
Polypoid Syphilitic Chancre of the Tonsil. G. Portmann.—p. 174.
The Menace from Typhus in Eastern Europe and Asia Minor.—A. Vaudremer.—p. 176.

Fat Grafts.—Mauclore expatiates on the numerous indications for and advantages of implants of adipose tissue and of the fatty bunches on the omentum, and reviews the literature on the subject. He has used fat grafts to isolate adherent tendons and muscles, to isolate nerves embedded in fibrous tissue, and to fill up depressions, to reinforce suture of the intestines, to plug and arrest bleeding in wounds of the liver and fill up the cavity after removal of a cystic tumor, to obliterate a fistula into the liver, to aid in suturing the uterus after myomectomy or amputation, to fill the cavity after an operation for osteomyelitis, to interpose between articulating surfaces, and to plug a persisting fistula into the pleura. The results on the whole have been very good in his own and others' experience. The reason why fat grafts have not been used more extensively seems to be on account of a mistaken impression that their vitality is very low.

*Radio-Active Mud in Treatment of Adnexitis. M. Chifoliau and H. Guillard.—p. 103.

*Diabetes and Acromegaly. Lerehoulet.—p. 106.

*Exophthalmos with Jugular Thrombosis. Cordier and Rollet.—p. 108.

Radio-Active Mud in Treatment of Adnexitis.—Chifoliau and Guillard have been utilizing the by-products of radio-active minerals, a radio-active mud, in cases of disease of ovaries and tubes, and have found it very satisfactory. They apply it in the vagina, a cylinder of the substance wrapped in gauze and molded to fit the lesion to be treated, while ice is applied to the abdomen. The mud is left in place for one or two days and after a pause of two or four days the application is repeated. The pain and fever seem to be reduced at once and the inflammatory process rapidly subsided, they say, permitting a conservative operation at need, the acute stage of the ovaritis or salpingitis being thus very much shortened. Sixteen cases are described in detail.

Diabetes with Acromegaly.—The circumstances of the case described confirm that alimentary glycosuria or diabetes observed with acromegaly is due to nerve irritation at the floor of the third ventricle, from enlargement of the sella turcica. Contrary to diabetes insipidus, which is due to the pituitary itself, the glycosuria type seems to be the result of irritation in the vicinity of the pituitary, not in the latter itself.

Exophthalmos with Jugular Thrombosis.—The protrusion of one eyeball occurred suddenly in the terminal phase of thrombosis in the jugular vein in a man of 30 with endocarditis and asystolia. The condition was like that with intermittent exophthalmos from venous stasis only it was permanent.

*Lipolysis in Fibromyomas of the Uterus. H. Keiffer.—p. 451.

*Radium Therapy in Menorrhagia and Metrorrhagia. P. Degrais.—p. 454.

Lipolysis in Fibromyomas of the Uterus.—Keiffer states that fibromyomas of the uterus may disappear during or after pregnancy by means of a complex mechanism, mainly through lipolysis, but associated with other degenerative processes. The details of lipolysis may be observed especially in the muscular fiber around the nucleus. The strands of connective tissue seem to resist longest the degenerative process. Toward the last the fibromyoma appears like a spongy tissue in the network of which is seen a complex mass in which fat droplets of various sizes, together with cellular refuse have accumulated. After childbirth some fibromyomas present the same characteristics as before pregnancy; others diminish in size, become softer, and seem to have disappeared, especially since the hemorrhages which accompanied them have ceased as well, but after three or four years the same fibrous bunches appear again and may develop into large growths. A third group of fibromyomas undergoes rapid and permanent retrogression.

Radium Therapy in Menorrhagia and Metrorrhagia.—Degrais having employed radium with success in numerous cases of menorrhagia and metrorrhagia, describes his technic and states what he regards as the indications for such treatment, namely, in cases associated with hemorrhagic metritis, uterosclerosis and fibromas. The results have been excellent, and on the basis of his experience with cases that have stood the test of time, Degrais believes that absolute cures can be effected by radium therapy.

Revue Médicale de la Suisse Romande, Geneva

March, 1920, 40, No. 3

Acute Appendicitis at Onset of Attack. E. Kummer.—p. 133.

*Influenza Does Not "Tuberculize." R. Burnand.—p. 145.

*Fixation Abscess in Influenza. L. Probst.—p. 159.

Critical Review of Procedures for Exploration of Stomach. E. Cottin and M. C. Saloz.—p. 163. Concl'n.

*Gastric Cancer with Pulmonary Lymphangitis. G. Turrettini and I. Gerber.—p. 177.

Does Influenza Predispose to Tuberculosis?—Burnand's experience at the Leysin Sanatorium confirmed the lack of any immunity to influenza in the tuberculous, but he was

unable to discover that influenza there or elsewhere had caused the flaring up of latent tuberculosis to any appreciable extent. There has been no recrudescence of tuberculosis throughout the country since the epidemic such as otherwise would be inevitable.

Fixation Abscess in Influenza.—Probst remarks that influenza is again the topic of the day in Switzerland, although the new epidemic is not so severe as in 1918 and 1919. His experience then and with recent cases has confirmed his previous announcements in regard to the benefit from a fixation abscess induced by subcutaneous injection of 1 c.c. of turpentine. He ascribes its efficacy to the hyperleukocytosis which it induces, as influenza is accompanied by pronounced leukopenia. He thinks this explains also why influenza is mild postpartum. The hyperleukocytosis of parturition renders the infection mild, and there is nothing so effectual, he declares, to induce hyperleukocytosis as the fixation abscess. He warns not to incise the abscess until the disease is subsiding (apyrexia), and then to make an ample incision and clear out the abscess thoroughly.

Pulmonary Lymphangitis from Gastric Cancer.—Turrettini and Gerber report a case of cancer of the stomach in a woman of 30 which ran its entire course without local subjective symptoms. After nine months of progressive weakness and anemia thrombophlebitis of the jugular and innominate veins led to palpation of a tumor mass in the stomach, soon followed by invasion of the lymphatics in the lungs by the malignant process. Necropsy showed that more than half of the walls of the stomach had been involved in the cancer.

Revue Neurologique, Paris

*Irritation in Pathology of Nervous System. Triantaphyllos.—p. 881.

*Suppression of the Babinski Reflex. Noïca and A. Radovici.—p. 891.

*Anyotrophic Paralysis Following Tetanus Antiserum. J. Lhermitte.—p. 894.

*Intraspinal Treatment of Neurosyphilis. G. Marinesco.—p. 901.

The Significance of "Irritative Phenomena" in Nervous and Mental Pathology.—Triantaphyllos defends the view that there is no such thing as a formula of cellular changes corresponding to so-called irritative lesions by which function is stimulated; that is, a formula that can be regarded as opposed to the destructive formula that diminishes the function. He holds further that every pathogenic agent and all pathologic conditions tend to abolish the function of the cell affected by the lesion. It is only when the pathogenic agent exerts an elective action on neurons that have an inhibitive effect on other neurons that the phenomena termed "irritative" appear. But these phenomena are not due to the fact that a so-called irritative lesion caused an increase in the function, but to the circumstance that a lesion with a destructive tendency has reduced inhibition (for the neurologic irritative phenomena) or has reduced the power controlling the normal ideation (for the psychic irritative phenomena).

The Suppression of the Babinski Reflex.—Noïca and Radovici give as the result of their experience that it is never safe to state whether the Babinski reflex is positive or negative if the foot of the subject is cold, as cold will often suppress the reflex temporarily.

Intraspinal Treatment of Syphilitic Disease of the Central Nervous System.—Marinesco reviews his experience in this line since 1910 and states that he has fourteen patients with tabes or general paresis whom he treated with salvarsanized serum over six and seven years ago. He gives a brief summary of three of the cases of general paresis in which the clinical improvement has persisted to date, except that one patient, a physician of 35, who served all through the war with devotion and efficiency, recently had a relapse and died insane. The woman of 41 and another man are in clinical health to date, eight years after commencing the treatment.

*Influenzal Meningo-Encephalitis. D. Pace.—p. 175.

*Multiple Cartilaginous Exostoses. G. Marsiglia.—p. 177.

Deficiency Phenomena. G. Molinari.—p. 182.

Influenzal Meningo-Encephalitis.—Pace reports a case of coma and fever in a man of 41 who had not felt quite well since influenza four months before. The symptoms indicated acute congestion in brain and meninges, not improved by venesection, but lumbar puncture the fourth day seemed to arrest instantaneously the morbid process. In a second case the predominant symptom was delirium with high fever, but it yielded in the same way at once to lumbar puncture. Lymphocytosis was pronounced in the fluid in both cases. His retrospective diagnosis was influenzal meningo-encephalitis. The involvement of the brain in influenza is rare; he says that only a few cases have been reported in the different countries, including L. Litchfield's four published in THE JOURNAL, May 10, 1919, p. 1345.

Cartilaginous Exostoses.—Marsiglia analyses the literature on this subject and expresses the opinion that the exostoses are not local processes but develop from some single cause. This may possibly be the same cause responsible for rachitis, the effect in some cases being the latter, and in others, these exostoses. In a personal case described in a young man there were signs of rachitis along with the thirty-six exostoses, and when some of the larger ones were excised, the bone marrow ran out like oil from the gap left in the long bone. A familial and hereditary character was evident in this case. The thyroid was normal in aspect, but the short stature and rather backward mentality suggested possible loss of balance in the endocrine system.

December, 1919, **3**, No. 12

Two Cases of Achondroplasia. S. Cavenet.—p. 705.

*Eczema in Infants. E. de Oyarzabal.—p. 712.

Eczema in Infants.—De Oyarzabal remarks that as the skin is so sensitive in children with eczema, it may be advisable to refrain from washing the eczematous regions with soap and water, and use olive oil, cold cream, a benzoin or a hot 3 per cent. solution of boric acid. The region in children should be covered with a bandage to protect against

scratching. If in the face, and if it itches much, it is better to give small doses of bromid or chloral to insure the child's sleeping. Eczema of the scalp, he says, readily improves under a 2 per cent. salicylated yellow petrolatum or oil containing 1 to 5 per cent. anthrasol, cleansing once a day with olive oil and occasionally washing with an infusion of chamomile. Eczema, rebellious to all other measures, may yield to roentgen-ray exposures. "With these, admirable results are obtained."

The Amino-Acids in Metabolism. E. Gómez. A.—p. 186.

*The Wassermann Reaction. J. Bejarano.—p. 195.

The Hygiene of Milk. G. Arbeláez R.—p. 205. Cont'n.

Estimation of the Clinical and Social Value of the Wassermann Test.—Bejarano insists that a decision as to whether a syphilitic can marry cannot be based on a single Wassermann test. A double plus reaction in inherited syphilis calls for treatment, and a triple plus reaction in acquired syphilis after a period of negative reactions justifies a prognosis of impending neurosyphilis. Even with negative blood reaction, an intense reaction in the cerebrospinal fluid suggests general paresis. He urges the appointment of a commission by the medical congresses to unify laboratory methods and control the work of different laboratories.

Revista Médica del Uruguay, Montevideo

February, 1920, **23**, No. 2

*Catatonia with Stupor and Uremia Following Influenza. Elio García.—p. 49.

*Headache with Mild Endocrine Disturbance. F. S. Garmendia.—p. 57.

*Psychology and Psychiatry. C. Payssé.—p. 61.

Catatonia and Uremia Following Influenza.—García knows of only two cases on record in which dementia developed complete in two or four weeks, but in the case he describes the interval from the onset of symptoms was only one week in the previously healthy young man. Catatonia then followed at once, with progressive stupor and reduction of all the vital processes, the young man lying like a living statue until death the third month. When first examined, three weeks after the onset of the apparently mild influenza, the blood serum contained 0.82 gm. urea per liter and the urine 9.5 gm., and the cerebrospinal fluid a few days later contained 0.48 gm. per liter. At this time there had been a brief period of delirium but the stupor and catatonia which then developed persisted without intermission to the last. In another case of influenzal psychosis the blood serum contained 1.2 gm. urea and the puncture fluid 1 gm., but recovery was soon complete.

Headache with Mild Endocrine Disturbance.—Garmendia reports two cases of headache for which thyroid insufficiency was evidently responsible, and which yielded to thyroid treatment. In another case, latent chronic suprarenal insufficiency was finally detected and under epinephrin treatment, supplemented by recalcification measures, the patient regained strength and the headaches disappeared. In his fourth case a young woman had violent headaches during the menstrual periods, with occasional milder headaches in the intervals, and menstruation was scanty and painful. Tachycardia, a soft pulse, and pains in the region of the ovaries confirmed the assumption of ovarian insufficiency, and under ovarian extract treatment there has been no return of the disturbances during the four months to date. The symptoms in the suprarenal case had been great weakness, frequent nausea, pains in the left hypochondrium, and intense and frequent headaches. Small patches of slight pigmentation were found in the axillae and at the waist. The headache in the thyroid cases was in the upper and front part of the head and lasted the whole day, the skin was dry, and the outer portion of the eyebrows was scant of hairs.

Psychology and Psychiatry.—Payssé is alienist to the Vilardebo Hospital, and he here devotes fifty-seven pages to analysis of the methods of psychology and the necessity for applying them in psychiatry.

Urobilinuria and Continuous Malaria Fever.—Reynolds reports the case of a youth who had been sent to him with the diagnosis of pulmonary tuberculosis plus whooping cough. He found urobilinuria and a continuous fever, and was impressed by the way the physical signs in the lungs changed their location. The urobilinuria pointed to the liver, but the liver was not tender and the urobilinuria fluctuated from day to day. On this basis malaria was suspected and under quinin the urobilinuria promptly subsided, the supposed tuberculous lesions in the lungs cleared up, and the supposed whooping cough disappeared. Whenever the quinin was suspended, the urobilinuria reappeared. This is the most constant sign of continuous malarial fever, he reiterates, and it rises and falls with the fever, and yields with mathematical precision to quinin, even when the fever resists the action of the drug.

Prophylaxis of Mercuric Chlorid Poisoning.—Pignetto pleads for measures to put an end to the numerous cases of mercuric chlorid poisoning among women. He has had thirty-nine cases in his service alone in the last five years out of fifty-five attempts at suicides by different means. Ten died of the thirty-nine mercuric chlorid cases. Among the measures which he advocates to repress this almost epidemic of chlorid poisoning, is the enlightenment of the public in regard to the agonies from taking this drug. Few realize the tortures to which they are subjecting themselves when they take mineral poisons which are not speedily fatal.

Lymphoid Foci in the Thyroid Gland in Addison's Disease.—In connection with the subject of lymphoid foci found in the thyroid gland in exophthalmic goiter, Dubois reports similar findings in six cases of Addison's disease, and states as the result of his investigations that in Addison's disease masses of genuine lymphatic tissue with typical germinal centers occur in the thyroid gland, and that this lymphoid tissue must be regarded as a heterotopic new growth, displacing the parenchyma. This new growth is not of an inflammatory nature, but is to be regarded as the result of an excitation arising from the suppression of the suprarenal system, which threw a heavier weight of responsibility on the thyroid gland. The formation of large follicles with germinal centers may have some connection with the status lymphaticus, which is constant in Addison's disease.

 *Suppurative Perimenigitis. P. Morawitz.—p. 294.
 *Syphilitic Aortitis. G. Hubert.—p. 317.

Residual Nitrogen After Nephrectomy.—Becher found a considerable increase of the residual nitrogen in the blood and tissues of a dog after nephrectomy. Retention alone cannot explain this; there must be increased destruction of albumin to account for all this waste.

Hypertrophy of the Pylorus with Pernicious Anemia.—Kleemann reports a case which confirms the frequent occurrence in pernicious anemia of symptoms which suggest cancer, and necropsy apparently confirms the scirrhous growth at the pylorus. But the microscope shows merely simple hypertrophy of the pylorus. It had developed in the course of the typical pernicious anemia in the man of 39. There may have been at first merely pylorospasm, but the hypertrophy soon followed. There had been also intermittent jaundice all through the disease, but the biliary apparatus seemed to be normal at necropsy, as also the pancreas and suprarenals, although there had been occasional alimentary glycosuria.

The Albumin Quotient in Urine and Blood.—Albert has materially simplified and shortened the technic for determining the ratio between the serum albumin and serum globulin in urine and blood serum. It is based on precipitation with trichloroacetic acid and centrifuging. This test with parallel tests with other technics confirmed its reliability.

Perimenigitis.—Morawitz reports three cases of what he calls acute suppurative peripachymeningitis. It developed in two girls of 15 and a soldier, in the course of staphylococcus sepsis. The inner aspect of the dura was normal, but the adipose tissue between the dura and the periosteum of the vertebrae and the ligaments had become transformed into an abscess. It reached from the lumbar region to the neck in one of the cases. Lumbar puncture released pus, but the mind was clear throughout in all. The legs and lower trunk were extremely sensitive but not the arms. The pains and tenderness were most pronounced in the back, and especially in the lower thoracic and upper lumbar vertebrae. No osteomyelitic foci could be discovered. In one of the cases this perimenigitis seemed to be the only localization of the infection. Operative intervention should be considered when the perimenigitis is diagnosed in time.

Syphilitic Disease of the Aorta.—Hubert insists on prolonged specific treatment and that it must be vigorous. His 300 cases included 25 per cent. with tabes. In 60 cases the interval since infection averaged over twenty-three years. The range was from four to over forty years. The aorta was affected in 70 per cent. of all the cases of visceral syphilis, and in 14.6 per cent. of the total 1,485 syphilitics. In private practice, Romberg found it in 26.2 per cent. Hubert's 1,485 syphilitics included 750 men and 726 women, but twice as many men as women developed the aortitis. The pain or ache behind the upper portion of the sternum is almost pathognomonic. Some say they feel as if a stone were lying on the heart; others say that something has twisted or torn in this region. The pain may spread to both sides, to the back or neck or left arm. About a third of the patients complain of shortness of breath on exertion or vague stomach disturbances. The complexion often recalls that of cancer patients, but the exaggeration of the second aorta sound is the earliest symptom in most cases. A systolic murmur in the aorta was evident in some position in 75 per cent. of his cases.

 *Gastric and Duodenal Ulcers in Children. P. Theile.—p. 275.

Gangrenous Erysipelas of Scrotum and Penis.—In See-mann's case deep-seated erysipelas had developed from a gunshot wound of the buttock and extended to the back, abdomen, thighs and genital organs, and the penis became swollen to twice its normal size. The scrotum was puffed up like a balloon. Seemann punctured to relieve the pressure on the scrotum, 30 c.c. of a turbid, bloody, serous fluid being removed from either side. Examination of the fluid revealed streptococcus in pure culture. The whole scrotum and the skin of the penis, with the exception of a small strip

of the prepuce, soon became gangrenous. The gangrenous tissue was cut away, leaving the testes, spermatic cords and penis exposed as in an anatomic preparation. In one month the wound surfaces had healed sufficiently to consider undertaking repair measures. There was nothing of the scrotum left that could be used for plastic purposes. Seemann did not anticipate good results from a new scrotum, so he decided to reconstruct merely the penis. He drew the left testis through the inguinal canal and embedded it in the preperitoneal fat directly under and medial to the anterior superior iliac spine, and sutured together over it muscle and aponeurosis, allowing for drainage. This procedure could not be applied to the right testis because of an abscess in the abdominal wall. Seemann therefore removed the right testicle. The margins of skin were used to cover in part the corpora cavernosa and corpus spongiosum. To prepare for the covering of the balance of the penis, the incision wounds on the abdomen were freshened and drawn together with wire sutures. Following Pilz and Böhrer, the fragment of prepuce was drawn down over the penis. A transverse flap was cut from the perineum, turned over 90 degrees toward the front, attached to the penis from below, and joined to the preputial fragment that was in place. A second long, wide strip was taken from the healthy portion of the lower abdomen and was used to cover the balance of the penis, being sutured to the preputial fragment, the perineal strip and the skin at the root of the penis. The end-result is entirely satisfactory. The penis is covered throughout with healthy and for the most part movable skin. The glans is exposed as after circumcision. The patient has no pain, and ability to cohabit has been preserved.

Spinal Protuberance After General Local Tetanus.—Brunzel reports a case of protuberance of the spine after tetanus in a girl of 9. It is the first instance on record, as far as he is aware, in which the patient recovered. The girl had been wounded in the left lumbar region by a charge of shot from a small shotgun used for shooting sparrows. The wound of entrance was about the size of a dime and located just below the twelfth rib. The kidney had been torn into three parts by the force of the explosion, as the gun had been fired at very close range. Twelve days afterward severe tetanus, with violent muscular spasms, trismus and fever, set in, but three months and a half after admission to the hospital the patient was dismissed with a small fistulous wound that had almost ceased oozing. She had had no spasms for more than two weeks. Shortly before the patient was dismissed it was noted that there was a small protuberance of the spine in the lumbar region. She could only bend at the hips; the back was held stiff. A roentgenogram revealed the presence of most of the shot in the region of the third and fourth lumbar vertebrae. The spine did not appear to be injured. The protuberance was evidently due to the extremely violent paroxysmal contractions of the muscles of the back, crushing vertebrae. Three years after the accident the patient had become a strong, healthy girl. The spine had recovered its elasticity, but the protuberance presented the same appearance as when the patient was dismissed from the hospital. Brunzel cites another case of a sergeant who suffered shrapnel injuries in the left humerus and in the left lumbar region. A month later terrible paroxysms of pain developed which were supposed to be due to an impinged nerve. A roentgenogram disclosed a shell fragment close to the second and third lumbar vertebrae. The spine was not injured. The pain crises continued and the patient had to be kept under the influence of morphin. An attempt to remove the foreign body had to be given up. In three or four weeks the pain crises gradually ceased and the patient recovered. A protuberance of the spine in the lumbar region was now discovered. On dismissal the back was still somewhat stiff, but the patient could stoop readily and was without pain. The discovery of the protuberance explained the clinical picture. The paroxysms of pain that had continued for weeks were without doubt due to tetanic muscle contractions from a purely local tetanus confined to the lumbar region.

Gastric and Duodenal Ulcers in Children.—Theile states that gastric and duodenal ulcers in children, while com-

paratively rare, are not unknown and occur much more frequently than is realized. Of 248 cases of ulcers of the gastroduodenal tract in children under 16, collected from the literature, there were 119 gastric ulcers and 185 duodenal ulcers. Of these cases, 89 were in boys, 98 in girls, and in 61 cases the sex was not mentioned. Theile reports a case of pylorus resection in a 2 year old girl, with good results, which he thinks will have the effect of increasing the confidence in this operation in the quite young. Tuberculous and uremic ulcers, and those in the new-born, give the least promise of success from operation. Although in typical marantic ulcers in infants the prognosis is very unfavorable, the good results secured from surgical intervention in the foregoing case will offer some encouragement. He describes further a successful operation for perforated gastric ulcer in a girl of 13. Appendicitis had been diagnosed as the idea of a perforated gastric ulcer was rejected as preposterous at that age. In a third case, gastro-enterostomy was done to relieve a hard duodenal ulcer, with stenosis of the pylorus, in a boy of 15, who had been presenting symptoms for about three months, vomiting at night, with great thirst. This is the youngest case of duodenal ulcer on record, he says.

Aorta Changes and Their Clinical Significance.—Hubert says that clinical changes in the aorta are a frequent finding in patients in middle age and in more advanced years. They are often noted when they do not seem to be causing the subject any trouble whatsoever. Nevertheless, they are usually of great significance, for almost without exception they are an indication of an organic pathologic condition in the aorta itself. One and the same symptom may be the expression of widely different diseases, and thus present a variable significance, from which fact diagnostic errors are likely to arise. Hubert takes this as his justification for discussing in detail the various diagnostic values that attach to the pathologic processes in the aorta. The changes in the aorta fall naturally into three classes: percussive, auscultatory and roentgenologic, of which the last is the most important. A diffused area of aortal dullness is a sure indication of a far advanced pathologic process. Whether sclerosis or syphilis of the aorta is present must be determined by other means, for in connection with aorta changes one must ever bear in mind the old saying: "The diagnosis must never be based on a single symptom." The accentuation of the second aortic sound, if accompanied by hypertrophy of the left ventricle and an increased blood pressure, indicates an induration of the kidney either from sclerosis or through chronic injury to the glomeruli. If the accentuation of the second aortic sound is only transitory, it will be shown by the fact that the increase in blood pressure will only be transitory. The most frequent cause for the accentuation of the second aortic sound is to be sought in the aortal wall itself. This symptom if present manifests itself early. Likewise, the most frequent cause for the systolic aortic murmur is not valvular trouble but some pathologic condition in the wall of the thoracic aorta.

The Peculiar Contour of the Lungs in Roentgenograms.—Chaoul states, on the basis of investigations conducted on living subjects and cadavers as well, that the peculiar contour that the lungs present in a roentgenogram is due to the blood-filled pulmonary vessels which appear as positive shadows. The appearance of a double contour often seen is not produced by a bronchial wall, as some have maintained, but is due, Chaoul thinks, to the shadows of blood vessels

running parallel to a bronchus. The crossings of the vessels and the bronchi cause the lighter and suddenly darker shadow streaks.

- *Pathology of the Vegetative Nervous System. F. Depisch.—p. 147.
- *Pathology of Peripheral Arteries. J. Wiesel and R. Löwy.—p. 197.

Pathologic Respiratory Conditions as Affecting Shape of Chest.—Wennekebach's article supplements one published in 1907 on the pathologic relations between the respiration and the circulation. He here discusses the six main factors influencing the form of respiration and shape of the thorax, ascribing much importance to extreme leanness as this allows the so-called asthenia shape of the thorax to develop even without any constitutional anomaly or congenital predisposition. He also emphasizes the importance of the muscles of the back in quiet, unconscious respiration as well as in forcible inspiration. He comments on the advantage of humming with the lips closed, as a breathing exercise and for study of the action of the abdominal muscles. With this, the diaphragm is drawn up extremely high in the chest as the humming continues to the limit of expiration. Coughing is still more instructive for study of the muscles involved in respiration. He recalls that the diaphragm like all other muscles is subject to reflex influences, and its excursions can be modified from distant points. When breathing quietly, with mouth closed, if the mouth is opened suddenly, the diaphragm rises a little. Continuing the even breathing with the mouth open, it is evident that conditions in the respiration are quite different from what they were before. The sinking of the root of the tongue when the mouth is opened may explain this difference in the tonus of the diaphragm. Whatever the explanation, there is no doubt that this modified behavior of the diaphragm is an element not to be overlooked in habitual mouth-breathing.

Drumstick Fingers.—Höglér has coined the term "acropachy," from *akron*, "tip" and *pachy*, "thick," to define the condition and differentiate it from acromegaly. It accompanies four groups of diseases: those with abscess in the lungs; malignant disease; processes in the liver, mainly hypertrophic biliary cirrhosis, besides, unilateral acropachy from compression by an aneurysm or joint lesion. In one of the four personal cases described, there were evidences of lymphogranulomatosis and infantilism with the acropachy in the youth of 17. Under roentgen-ray treatment of the principal lymphogranuloma—in the chest—the tumor retrogressed almost entirely, and the fingers returned to approximately normal shape and size. The changes in the fingers with tabes and syringomyelia are not of this acropachy type. The various theories as to the etiology are compared, and the secondary and curable nature of the acropachy is emphasized.

Pathology of the Lungs.—Eppinger and Wagner reiterate that anything tending to modify the circulation and metabolism of the blood is liable to induce appreciable disturbance in the circulation as a whole even with a comparatively sound heart. In the last eight years they have encountered five cases in which the total circulation was much impaired from primary endarteritis of the finer ramifications of the pulmonary artery; the main artery was intact. They diagnosed the condition during life in three of the cases, the practical obliteration of the finer branches throwing extra work on the right ventricle alone, and this had become enormously hypertrophied. The left ventricle formed merely a crescent lying on the right ventricle, and the atrophy extended to the left auricle, which may even be smaller than usual, in comparison to the size of the right heart. The integrity of the valves is characteristic of these cases. They have found fourteen similar cases on record; of the total nineteen cases, eleven were in men and ten of the patients were between 20 and 40; one was over 60. The pulse is small and there is much cyanosis and edema when the right ventricle fails to do its work properly, but there is very little

dyspnea. There may be occasionally a tendency to bleeding from the lungs. Before this phase is reached, the extremely enlarged right heart may be the only sign of the condition; cases are known in which there was some cyanosis early. A diffuse darkening of the lung in the roentgen picture testifies to stasis.

Bulbar Disease with Irritation of Only Half of the Vegetative Nervous System.—Depisch reports a case of this kind and compares it with others on record. They all testify that the fibers of the vegetative system become crossed on their way to the periphery, the same as the motor and sensory fibers. The primary cause was usually some localized hemorrhage in the medulla oblongata, entailing bulbar paralysis. The unilateral symptoms included a higher local temperature, the unilateral action of drugs, etc. He discusses the mechanism of the different symptoms, and gives considerable bibliography.

The Peripheral Arteries in Acute and Chronic Diseases.—Wiesel and Löwy exclaim that the peripheral vascular system has never been thoroughly studied. Their own research on twenty cadavers after long clinical study of the cases demonstrated that in all those in which death was due to insufficiency of the circulation, the middle coat of the smaller arteries showed constantly edema, degenerative processes or foci of calcification, etc., or all combined. These regular changes may be associated with myocarditis or they may alone dominate the clinical picture. They explain the inefficacy of digitalis in certain cases. The more advanced the peripheral changes, the less the action of digitalis, so that these changes should be suspected whenever digitalis fails in its expected action. This assumption is further justified by the efficacy of strychnin in raising the tonus of the vessels in such cases. These changes in the peripheral vessels must be an important factor in the pathology of stasis, especially in internal organs. They give five plates showing the changes found in the peripheral arteries and veins in their twenty cases.

Hemorrhagic Diatheses.—There has been an increase of hemorrhagic diatheses, Kirch reports, during the war period, usually associated with scurvy. The various forms are clearly distinguishable hematologically. Aside from infections, the restricted war diet was the cause. A hemorrhagic diathesis, he says, presupposes vessel injury, and as blood platelets are an important factor in blood coagulation, they may have the intravascular function of making the vessel walls more dense. A deficiency in blood platelets might thus contribute to the permeability of the vessels.

Treatment of Trichophyton Infection.—Sachs commends intravenous injections of a 40 per cent. solution of hexamethylenamin in the treatment of deep trichophyton infection, with large nodules. As a first dose 6 gm. (15 cm. of fluid) are injected; on the second or third day after the first injection the dose is increased to 8 gm. In one case 8 gm. were given as a first dose, which was increased to 12 and 14 gm. The number of injections required and the exact quantities of hexamethylenamin that will be needed cannot be definitely stated in advance. Of ten patients so treated, one was cured after a single injection of 4 gm., another after three injections of 4, 6 and 8 gm., respectively, in ten days; another patient received four injections (once 6 gm. and three times 8 gm.), and was cured in fourteen days.

THE FUTURE OF OBSTETRICS AND GYNECOLOGY AS A SPECIALTY*

REUBEN PETERSON, M.D.

ANN ARBOR, MICH.

Allow me to express my deep appreciation of the honor conferred on me at the last meeting of the section in selecting me to preside over this year's deliberations.

The honor, however, carries with it the obligation to deliver the chairman's address, the selection of the subject being left to your presiding officer. For a time I had it in mind to dodge the issue, as it were, and address you on a scientific subject. This course has decided advantages, since we physicians are accustomed to papers on scientific subjects, as we are wont to inflict them on a long suffering medical public on all occasions. On the other hand, the chairman runs no little risk of having his production, his address, far outclassed by the other scientific papers presented at this meeting. Consequently I have decided to attempt the "address" with the hope of holding your attention on account of the subject selected, since your presence here denotes that you are more or less interested in obstetrics and gynecology, although you may not be specialists.

THE SPECIALTY OF OBSTETRICS AND GYNECOLOGY

I would particularly call your attention to the title of my address, since it indicates the position I have for a long time taken and am prepared to defend regarding the specialty we are interested in. I beg you to note that the two divisions of the specialty have been linked together, and that the future of not two specialties but a single specialty will be considered. Again note what perhaps is a small matter, yet may not be without significance: The specialty is designated as obstetrics and gynecology and not the reverse. If obstetrics may be defined as the care of women during pregnancy, labor and the puerperium, and gynecology as the science of the diseases peculiar to women, it seems illogical to place what has to do with disease in advance of what has to do with care whereby disease may be prevented.

We are all more or less familiar with the discussion which has been carried on during the last twenty or more years regarding the place of gynecology as a specialty. While it probably has had little effect one way or another, for man's course in life is determined by inclination and self interest and not by what other people may say, it has shown certain fundamental

defects in our medical make-up. The gynecologists as a class have deliberately confined themselves to the surgical aspects of the diseases of women, some of them openly declaring they knew nothing of obstetrics and did not care to learn. As surgeons of a special part of the human body, they have become masters of their art. It was inevitable, however, that they should become discontented with a small field of surgery, and that they should ambitiously push on toward adjacent fields. Thus we see abdominal linked to gynecologic surgery, and the gynecologist operating on men as well as women on the ground that he is an abdominal surgeon as well as a gynecologist.

The general surgeon was quick to see the inconsistency of such a position, and declared that it was time to do away with a specialty that no longer fulfilled the requirements of a specialty. The assertion that gynecologic surgery is after all merely surgery of a special field and that it can be acquired by any surgeon who is willing to devote the necessary time to its mastery, and hence should be included in general surgery, has had more and more advocates as time has gone on. Thus we see the tendency to combine gynecologic with general surgery in hospitals and teaching institutions.

It is obvious that the gynecologist would have escaped the embarrassing position of being "hoist with his own petard" had he stuck to his specialty, or, rather, enlarged his specialty so as to include all conditions and changes in the female genital tract in which his special work naturally lies. This would have led him to devote more time to the field of obstetrics, not necessarily the actual practice of obstetrics, for that is a matter of detail to be worked out by each individual, but paving the way for his true mission as a specialist, the prevention rather than the cure of disease.

The truth of the matter is, if we are honest enough to admit it, that the gynecologist has only himself to blame for the present condition of affairs. He threw himself into the development of pelvic surgery to such an extent that things outside of the operative part of one division of the specialty failed to interest him. At the society meetings he would spend hours in the discussion of operative technic, and suddenly feel the need of fresh air when a paper was read on a non-operative topic equally important and necessary to his specialty as it should have been practiced. He was bored to extinction by every part of obstetrics, everything connected with the proper conduct of pregnancy, labor and the puerperium, which if uniformly carried into effect would have made a larger part of his operative work unnecessary. For, with the exception of tumors and the results of venereal infection, the greater part of the gynecologist's work has been

* Chairman's address, read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

devoted to the task of restoring parts or functions rendered defective by neglect or bad management during pregnancy, labor or the puerperium.

Both in theory and in practice we are very apt in this country to treat too lightly the words "specialty" and "specialist." It is the common experience of heads of departments in hospitals and medical schools to receive applications from practitioners with little or no experience for opportunities to become specialists in different lines of work. It is no uncommon occurrence to receive a letter from some one ambitious to become a specialist in gynecology asking to be appointed chief assistant for a period of six months or more. The letters go on to explain that the writers have performed quite a number of abdominal operations successfully, but that they want a larger experience than their practice affords before taking up gynecology as a specialty, with never a word about obstetrics, except that they have given up obstetric work with the exception of the operative part—not a word regarding opportunities in the clinic to work out certain nonoperative problems in which they should be interested. Such things apparently never have been thought of; ambitious to a degree, the applicants want experience which not infrequently they offer to pay for, whereby they may devote their whole time to surgical gynecology, through which they plan to restore to health women suffering from lack of care during childbirth.

Where lies the blame for such a misconception of the requirements of a specialty? Why is it that men above the average intelligence, as shown by their success in practice and their medical standing in their state, should think of a gynecologist merely as a man who is devoting his life to surgical carpentering work in a special field? Is not the answer that the medical schools and hospital clinics must assume the blame fundamentally in that they have divorced obstetrics from gynecology, belittled the former and for various reasons, not the least important being economic, have given undue prominence to the surgical aspects of the latter? The result is that the ground work absolutely essential for one aspiring to devote himself to one division of the specialty of obstetrics and gynecology is lost sight of and there is a wild scramble for a short cut to fame and fortune, usually through the dexterous handling of the scalpel.

TRAINING OF THE SPECIALIST IN OBSTETRICS AND GYNECOLOGY

Obviously there are two ways of becoming a specialist in obstetrics and gynecology—one by way of practice, the gradual elimination of all medical work except in the field the practitioner is especially qualified for and interested in, the other by way of the large medical school and hospital clinics in obstetrics and gynecology. Many eminent obstetric and gynecologic specialists have achieved distinction through the first route. Financial necessities and lack of opportunity will always compel certain members of the profession to adopt the practice route toward specialism. In fact, if the narrow training in some of the hospital clinics is continued, probably better specialists in obstetrics and gynecology would be produced through the practice than the hospital route, owing to the general broad training which must result from the work of a studious, conscientious and capable general practitioner during the time he is preparing to specialize. Handicapped by the necessity of earning a

livelihood while trying to perfect himself in his specialty, such a man, however, is always open to the temptation of choosing the path of least resistance, the surgical end of a specialty to the neglect of the ground work which, it is maintained, is absolutely essential to specialization in any field. Overwhelmed, buried by routine surgical work in a comparatively small field, he either remains content with a large income, or else satisfies his discontent by enlarging his surgical field and joining that large and it must be confessed ever enlarging company, men who started out to be obstetricians and gynecologists but ended in being general surgeons with a fondness for gynecology.

If there be a future for obstetrics and gynecology it must come, I believe, from the departments in the medical schools and from hospital clinics organized and maintained on the right basis. If the two divisions of the specialty be united it will flourish and be of immense benefit to womankind and future generations. If the two divisions of the specialty be separated in teaching institutions and in hospital clinics, in a generation or two at the farthest there will be no specialty of obstetrics and gynecology, nor will there be specialists in either of the two divisions. Obstetricians will cease to exist because the brightest of the rising medical generation will refuse to enter a specialty in which they are known as man midwives, where the work is of the hardest and the compensation very unsatisfactory. The surgically inclined bright young medical graduates of the future will certainly not choose gynecology as a specialty—why should they when they can be enrolled in a department of general surgery and become trained general surgeons of all parts of the human body?

It is time that the medical schools recognize the manner in which the obstetric teaching clinic has been neglected in the past, and take steps to see that such conditions are remedied. The obstetric teaching material must always be a great expense to an institution, for it is almost entirely composed of so-called charity cases. Women unable to meet the expenses of confinement seek the services of the indoor or outdoor departments of the obstetric clinic attached to a teaching institution because they have confidence that they will be well cared for. In order to avoid the great expense of providing adequate hospital teaching material for senior medical students, we see even today the continuance of the outpatient obstetric department where the student cares for the lying-in woman in her home, sometimes under, but more often without, competent supervision. Why this survival of a most time-wasting and illogical method of instruction in this particular branch of medicine? The explanation usually offered that the student by this method is taught under conditions he will have to meet when he begins practice does not explain why such a system is not in vogue in other teaching departments. Why not teach surgery and general medicine in the tenements? Surely the practitioner will not always be able to send his medical and surgical patients to a hospital, and must perforce treat fractures or pneumonia at the patients' homes. The true reason is that it is cheaper to build up an outpatient obstetric clinic with its wasteful and oftentimes poorly supervised teaching than to meet the expense of an adequate hospital inpatient clinic.

Almost any teacher of obstetrics will acknowledge that he prefers to instruct with hospital patients; but, he adds, for certain reasons the number of hospital obstetric beds at his command is not large, and hence

he utilizes the outpatient obstetric clinic to make up the deficiency. Would the heads of the departments of medicine or surgery take the same attitude? If their departmental teaching material were inadequate would they arrange for groups of students to be taught in the tenements? I think not. They would send forth a cry from the house tops about the shocking dearth of material until the governing body of the school or some benevolent gentleman or foundation provided for their teaching needs.

Why then the meek and lowly obstetrician? Is it true that he merits the gibe thrown at him by a gynecologist in a recent presidential address, who makes use of this remarkable sentence: "I may be wrong, but I have always maintained that a practitioner of medicine who is temperamentally fitted for the practice of obstetrics is entirely unfit to practice selected surgery or gynecology"? This is more than a gibe; it is a challenge. It says in substance to the obstetrician that he is a man infinitely inferior to the gynecologist. To be sure, he has certain bovine qualities fitting him to sit patiently by the bedside until a woman has had her baby; but perish the thought that he is in the same class with the brilliant, dashing gynecologist with his God-given surgical abilities. To make doubly sure that the obstetrician will keep his bovine hands off the surgical side of the specialty of obstetrics and gynecology, the same essayist advocates that "the teacher of gynecology in cooperation with the psychiatrist of our medical schools should aid in selecting and directing men because of special fitness to the pursuit of this or any other important specialty." There are certain merits to this suggestion for, if during the course of this remarkable mental test these two collaborators, the gynecologist and psychiatrist, by any chance were to run across an applicant who had ambition to become an expert in everything, physical and functional, pertaining to the genital tract of women, it would be comparatively easy to have such a person become either a temporary or a permanent occupant of the psychiatric clinic.

The truth of the matter is that the obstetrician without adequate training in gynecology is handicapped as much as but no more than is the gynecologist without obstetric training. Both are unfinished products, and neither can afford to reproach or insult the other. Their deficiencies cannot be made good by adding diseases of children or abdominal surgery to their respective fields of labor.

As a matter of fact, the future of the specialty of obstetrics and gynecology depends on the policy of the medical schools toward the specialty in the next decade. They must face the issue now in order to provide for the future. If adequate funds and facilities are provided for departments of obstetrics and gynecology, and the two divisions combined under one head, the specialty will flourish; the subjects will be well taught, and high grade research work will be turned out. If, on the other hand, the policy of selecting separate heads for obstetrics and gynecology prevails, the reverse will take place. Obstetrics will languish because opportunities will not be afforded the department to consider and treat the results of obstetric complications and errors. Gynecology, separated from obstetrics, will tend to become more and more a surgical specialty, for reasons already set forth, and there will be no legitimate excuse for not making it a part of general surgery. Clinging with desperate grasp to abdominal surgery will not save it, for the

general surgeon is or should be a master of that part of surgery. Inevitably the chairs of gynecology will disappear, possibly weakly nourished for a while under titles such as professor of clinical gynecology, but eventually they will be absorbed by general surgery. Vain will be the appeals to avert the inevitable. Talk about research in gynecologic fields or superior work of the gynecologist as compared with the general surgeon will fall on deaf ears. United with obstetrics, gynecology will survive; separated, it will gradually cease to exist.

Time does not permit, nor is this the occasion to take up in detail the organization of the ideal department of obstetrics and gynecology. It remains to consider only one feature of such a department, since the future of the specialty under consideration will depend on how well this part is provided for. I refer to the opportunities that will be furnished young graduates to spend five or more years in equipping themselves for their special work. No matter what may be the permanent personnel of the department, it is essential for the future of the specialty that a way be provided for the thorough training of these young men in obstetrics and gynecology. It goes without saying that they should be recompensed enough for their hospital and teaching work to keep them free from financial worries. Their hospital service should be so arranged and graded that they will be as much at home in obstetrics as in gynecology, and vice versa. In fact, the two divisions should be treated as one subject, the patients on whom the studies are being conducted being in different groups for hospital administrative purposes only.

It is comparatively easy under such a system to see that the surgical side of the specialty is not over-emphasized. While in five years the assistant naturally becomes a trained obstetric and gynecologic surgeon, it is possible during this time to interest his eager young mind in other than mechanical problems. While he will be interested in surgery, he will recognize its limitations and be equally if not more interested in problems that will make surgery less and less necessary.

With a man so trained it makes no difference, if he goes into practice, instead of continuing his academic career, whether he decides to be a specialist in obstetrics and gynecology, or chooses to devote his time to one division of his specialty. One need not worry about the hardships of being up all night with a confinement case and then being obliged to do difficult hysterectomies the next day. These are details for each man to work out. So far as the future of obstetrics and gynecology is concerned, I myself am interested only in seeing that he keeps the faith and finds enough in his specialty to interest him so that he will do his regular work well and add a little something to the sum of human knowledge. Well grounded in obstetrics and gynecology, the specialty of his selection, I know that he will be interested in everything connected with it, and that, being interested, he will not be chasing after "the false gods" who seem to trouble some people so much.

RELATION OF ABDOMINAL SURGERY TO OBSTETRICS AND GYNECOLOGY

Finally, what about the relation of abdominal surgery to obstetrics and gynecology? If the preceding argument be correct, why is it necessary or even wise to include papers on abdominal in contrast to pelvic sur-

gery in the work of this section? The wisdom of such a course is at once apparent if it be borne in mind that the trained obstetric and gynecologic surgeon must be versed in abdominal as well as pelvic surgery in order to be competent to meet the emergencies which will arise in his special surgical work. While making no claims for specialization in abdominal surgery, the obstetric and gynecologic specialist must be prepared at any moment to resect the intestine and care for the appendix and gallbladder, if such surgery be demanded when the abdomen is opened for pelvic disease. This is only justice to the patient, and is common sense as well.

In order to be competent in surgical work of this description the obstetrician and gynecologist must not only have had the necessary technical experience but must be conversant with the literature and the constant improvements taking place in abdominal surgery. Hence it is fitting and a wise practice to include papers on this allied field of surgery in the work of the section.

Actual experience and technical skill in abdominal as contrasted with obstetric and gynecologic surgery should be acquired in departmental hospital clinics by cooperation with the general surgical clinics. Arrangements can easily be made for interchange of services at some period of the training, to the mutual benefit of the members of both the obstetric and gynecologic and general surgical staffs. In fact, this principle of free interchange of services should not be confined to surgery alone, but should apply to all departments of the hospital, where such an arrangement will make for better training in obstetrics and gynecology.

RECENT STATISTICS OF HEART DISEASE

WITH SPECIAL REFERENCE TO ITS INCREASING INCIDENCE *

FREDERICK L. HOFFMAN, LL.D.

Third Vice President and Statistician, Prudential Insurance Company of America

NEWARK, N. J.

The statistics of heart disease are probably the least satisfactory of medical statistics because of the apparent impossibility of a precise and inclusive definition. No disease better emphasizes the principles and suggestions laid down by the late Dr. Charles A. Mercier, on the subject of causation, with special reference to causes of death. Mercier's work on "Causation and Belief" should be read by all who desire to do full justice to controversial questions in medicine concerning the so-called causes of disease or death, or the conditioning circumstances affecting the results of treatment. As observed by Mercier: "The cause of death is always a function of two variables—the power acting to maintain the unchange that we call life, and the action or actions that increase the work that the power has to do." He refers to a definition adopted by the registrar general, observing: "The fatal manifestation of a disease is, I surmise, what the registrar general means by a terminal condition or mode of death; but as he gives no indication whatever as to what he does mean, this can be no more than a surmise. In

such cases the disease may appropriately be called the principal cause of death, and the manifestation the precipitating or subordinate cause of death."

If so acute a mind as Mercier's could not arrive at a clear understanding of the terminology of disease, it is certainly a hopeless task for an average mind to attempt what seemingly defies analysis; but as a practical question it may safely be asserted that the ordinary definitions meet all reasonable requirements and that our vital statistics are approximately trustworthy except so far as modified by important and possibly far-reaching changes in the practice of classification. To no disease perhaps does this conclusion apply more than to heart disease, which, of course, is not a specific term but rather one which has simply the sanction of long continued use. In the earlier statistical reports, sudden death, for illustration, is of frequent occurrence, but is relatively rare in modern mortality investigations. As has been said by Dr. Theodore Fisher, "When we speak of sudden death, both medical men and those without medical training generally think at once of the heart"; but this by no means justifies the classification of a sudden death as being attributable, without the chance of error, to a diseased condition of the heart. There is no more illuminating discussion of sudden deaths than the treatise by Brouardel, whose masterly analysis brings out the fact that sudden deaths due to lesions of the circulatory system are by no means the only important causes or conditioning circumstances. He directs attention, for illustration, to lesions of the respiratory system, modifications of vascular tension, lesions of the digestive system and of the female genital organs, sudden death in fevers and in diabetes, diseases of the kidneys and alcoholism.

What is true of sudden death is even more true of dropsy and old age. These earlier terms, common in the practice of medicine fifty years ago, are now practically obsolete, it being clearly recognized that dropsy, for illustration, is a symptom and not a disease within the strict definition of the term. It is therefore grotesquely erroneous to compare the mortality from heart disease in modern registration reports with the returns of a generation ago, without the required correction, which frequently cannot be made for want of access to the original material. These remarks at the outset emphasize the urgency of extreme caution necessary in discussions of the changes in the incidence of diseases of the heart and circulatory system frequently bordering on the ridiculous and the grotesque. Before much progress can be made in scientific discussions of so-called heart disease, much further research in clinical medicine is imperatively called for.

No one has more clearly recognized this need than Sir James Mackenzie, perhaps the foremost authority on heart affections, and now the director of the Institute of Clinical Research of St. Andrews' University, Scotland. In his opening address, Sir James took occasion to lay it down as a first principle that, "as disease is made manifest to us only by the symptoms it produces, it is imperative that the first step should be to understand the nature and significance of symptoms." Calling attention to the vast amount of superficial and frequently thoroughly inaccurate information, he refers to the question of heart murmurs as evidence of heart impairment, although "the knowledge of how to assess the value of murmurs is lacking." Referring also to the practice of life insurance examinations for the purpose of ascertaining heart impairments, he remarks that life insurance examiners, whose duty it is to assess the

* Read before the Association of Cardiac Clinics at the New York Academy of Medicine, New York, Feb. 26, 1920.

value of symptoms, have not yet awakened to the fact that the methods employed are but a species of guess-work, and that they have not yet realized that accurate knowledge of this kind is absolutely necessary to the progress of medicine. Or, regarding the work of the ordinary doctor, who, he points out, "should not only be able to recognize the signs of disease, but able to say how much work a man with a given impairment should be able to perform," he comes to the lamentable conclusion that "this is the kind of knowledge which nowhere exists." This address by Sir James Mackenzie,¹ next to the work by Mercier, is one of the most valuable foundations for sane and conservative views on a subject which imperatively demands much more qualified consideration than it has thus far received, on the part both of the medical profession and of the laity.

HEART DISEASE AMONG MEN OF MILITARY AGE

It would obviously carry me entirely too far if I were to enlarge further on the clinical research aspects of heart affections and the problem of possibly profound changes in the relative rate of frequency occurrence during recent years. But I may properly direct attention to the importance of heart disease in childhood and youth, which has been made the subject of an admirable discussion by Dr. Charles W. Chapman, and the even more important question of "disordered action of the heart" (D. A. H.) or "valvular disease of the heart" (V. D. H.), in its relation to military service. The last named subject has been made one of extended inquiries by the Medical Research Committee, which include a brief but important discussion of terminology and an outline of symptoms, with a particular bearing on questions of statistical analysis. This work concludes with the suggestive observation that "the high incidence of the condition amongst men of sedentary occupation, and the frequency with which these men fail during training, call for more tender methods in the initial stages of training the conscript who for years has been accustomed to taking no exercise." This conclusion is applicable to the problem of occupational therapy as much as to the more restricted field of military usefulness. The work emphasizes the practical possibilities of heart disease prevention, and suggests a reconsideration of much of the advice summarized under the title of "What Heart Patients Should Know and Do," by Dr. J. H. Honan.

The relative frequency of heart diseases among men of military age has now been ascertained with reasonable accuracy, just as this has been the case in life insurance experience. In the latter, however, a certain element of selection operates, which is practically absent in military experience under the universal draft. The ratio of heart impairment in the army experience, represented by 85,143 cases, was 26.26 per thousand examined, or not quite 3 per cent. The rate was highest for the state of Washington, or 61.55 per thousand, and lowest for Wyoming, or 13.47 per thousand. It may be questioned whether the draft experience was sufficiently large and based on uniform methods of examination to justify final conclusions regarding the relative incidence of heart disease in different sections of the country.

The foregoing observation refers exclusively to valvular disease of the heart and endocarditis. Cardiac

hypertrophy and cardiac dilatation are represented by an impairment rate of 4.65 per thousand examined, the range having been highest for Nevada, or 10.63, and lowest for Arkansas, or 1.57 per thousand. Myocarditis and myocardial insufficiency caused an impairment rate of 0.72 per thousand, having been highest for Maine, or 16.40, and lowest in the District of Columbia, or 0.17 per thousand.

Combining all forms of organic diseases of the heart, the total rejections on this account were equivalent to 30.74 per thousand examined, the rate having been highest in the state of Washington, or 68.84, followed by Maine, with a rate of 55.70; Utah, with a rate of 54.60; Michigan, with 50.30, and Maryland, with 46.58 per thousand. It would not seem safe to rely on these returns for a true measure of the geographic incidence of heart disease, but the data are suggestive of a further inquiry into the facts. It may be suggested in this connection that much more extended medical consideration should be given to the statistical results of the defects found in drafted men, as presented in a Senate report to the Surgeon-General of the Army by Lieut.-Col. Albert G. Love and Dr. Charles B. Davenport. The conclusions of these officers on the general subject of organic diseases and defects of the heart are given in full as follows:

This group, which includes valvular disease of the heart, cardiac hypertrophy, cardiac dilatation, myocarditis, myocardial insufficiency, and endocarditis, is second in importance only to the great group of mechanical defects. Valvular disease of the heart was recorded in over 88,000 cases, cardiac hypertrophy in 11,389 more, myocarditis in 1,792, and endocarditis in 2,782. Altogether the group contains over 120,000 cases, or about 5 per cent. of the men examined. Of the 120,000 odd cases of organic defects of the heart, a large proportion properly enough was rejected for military service of any sort; namely, 90 per cent. There were, however, accepted for general military service, 2,872 cases of mitral insufficiency and 300 cases of mitral stenosis. One thousand one hundred and fifty cases of mitral insufficiency were placed in the limited-service group. Practically no cases were regarded as "remediable."

Recalling the words of caution of Sir James Mackenzie, it may safely be concluded that qualified ability for heart examinations on the part of many of the physicians employed in the draft examinations was wanting to give to the statistical results a full measure of scientific finality; but in a general way they may be relied on as sufficient for the purpose of emphasizing the important conclusion that all forms of heart impairment are not likely to exceed in relative frequency 3 per cent. of the men of military age, or about the same as were rejected on account of pulmonary tuberculosis (29.77 per thousand).

The results of life insurance experience are less applicable to practical requirements on account of the fact (1) that obvious cases of heart impairment do not present themselves for examination, and (2) that, in the words of Sir James Mackenzie, the methods of examination have hardly been sufficiently perfected to justify the rejection of a fair proportion of cases on the basis of mere murmurs, the true nature of which is not understood at the present time. In the experience of the Prudential Insurance Company of America, during the period 1915-1918, the rejections on account of heart impairments have been 24.4 per thousand examined, but the fact must not be overlooked that the practice of different companies varies and that while some are extremely cautious, others are grossly

1. The views of Sir James Mackenzie, in a more convenient form, are set forth in his treatise, "Principles of Diagnosis and Treatment in Heart Affections," London, 1916.

negligent in fully safeguarding their own interests against the ever-present risk of adverse selection.

INVESTIGATION OF THE MEDICO-ACTUARIAL COMMITTEE

An important contribution to the subject is the investigation of the Medico-Actuarial Committee into the mortality of males from organic diseases of the heart, which shows that the rate of mortality increases in insurance experience in about the same manner as

among the public at large. Table 1 exhibits the mortality rates from diseases of the heart per 10,000 exposed to risk, according to the duration of insurance, for the three age periods 15-29, 30-44, and 45 and over.

The medico-actuarial experience is most suggestive as regards the relative incidence of heart diseases at different periods of life for the two sexes. Table 2

TABLE 2.—PERCENTAGE OF DEATHS FROM ORGANIC DISEASES OF THE HEART TO ALL CAUSES *

	Ages at Entry		
	15-29	30-44	45 and Over

to risk, according to divisional periods of life, with distinction of sex, disclosing practically identical results for both males and females.

STATISTICAL RESULTS OF THE PRESENT INVESTIGATION

Table 4 shows the mortality from different forms of heart disease in the United States registration area during selected years sufficient for the purpose of indicating the trend of the recorded mortality figure. This figure must not be confused with the probable actual mortality, which cannot be ascertained at present with-

out a thoroughly qualified reexamination of original death certificates, to preclude the risk of serious errors in the earlier classifications.

It will be observed that in this table the rate of deaths from pericarditis and acute endocarditis have decreased, and quite materially so. In contrast, all forms of heart disease have increased from 131.9 per hundred thousand of population in 1900 to 169.0 in 1918. Within recent years the practice has become almost uniform for registration officers and others concerned with the tabulation and analysis of causes of death to amplify more or less doubtful death certificates by means of subsequent correspondence with the attending physician. In the case of the Prudential, probably not less than 10,000 letters a year are sent out to correct original errors, which materially changes the

TABLE 4.—MORTALITY FROM HEART DISEASES, U. S. REGISTRATION AREA, 1900-1918

Year	Death Rates per Hundred Thousand of Population				
	All Forms of Heart Disease	Pericarditis	Acute Endocarditis	Organic Heart Disease	Angina Pectoris
1900.....	131.9	2.6	11.9	111.1	6.4

1918.....	169.0	1.1	8.2	152.3	7.4

results of recent years when compared or contrasted with the past. It is regrettable that so much correspondence should be necessary, frequently to the annoyance of the attending physician, who alone is in a position to make out the original death certificate in exact conformity to rules of statistical practice as issued by the Census Office.

Table 5 shows the mortality from heart diseases in the original registration states, or such as constituted the registration area of 1900, being chiefly the states of New England, New York and New Jersey. In these states there has apparently been an increase of 52 per cent. in the mortality from heart diseases; but a large

TABLE 5.—MORTALITY FROM HEART DISEASES IN THE TEN ORIGINAL REGISTRATION STATES

Year	Population	Number of Deaths	Rate per 100,000 of Population	No. Deaths to Every 100 in 1900
1900.....	19,685,989	26,879	136.5	...
1905.....	21,431,243	34,636	161.6	118

1917.....	26,658,060	55,425	207.9	152

proportion, if not the major part of this increase is attributable to changes in death certification and classification, or the correction of death certificates in amplification of the original cause of death.

How far this conclusion affects the returns for a state like Massachusetts, where the subject has received careful consideration for many years, is shown in Table 6, in which separate age periods are considered in detail for quinquennial periods, commencing with 1868 and ending with 1917. This table is extremely suggestive and clearly emphasizes that the larger portion of the actual increase in the combined rate falls on the age period 40 and over, when, of course, heart diseases are relatively more common than at the younger periods of life. No convincing explanation has been forthcoming why the deaths from heart disease at ages 60 and over should have increased from 414.2 per hundred thousand of population to 1,613.5 during a

period of fifty years. There certainly is nothing startling in the textbooks on the subject which would explain this extraordinary increase, if true, as a pathologic phenomenon similar to the considerable increase in the cancer death rate, to which every writer on the subject gives more or less extended attention. The heavy rise in the incidence of heart affections in old age is, therefore, probably much more apparent than real, and in all probability chiefly the result of formerly erroneous methods of death classification and the transference of deaths formerly classified as dropsy, old age, sudden death, etc., to the more specific group of heart affections.

It may be useful to consider briefly here the relative incidence of different diseases, chiefly in adult life, and Table 7 presents the proportionate mortality from different causes, proving conclusively that, without reference to sex, heart diseases as a group are the most important affections, constituting 18.8 per cent. of the mortality from all causes at ages 40 and over. It is not conveniently possible to give this information by sex; but if the analysis were limited to females, cancer would occupy a much more important, if not a leading position in the relative standing of the different diseases.

Equally important is the fact brought out by the table that heart diseases at ages 40 and over constitute 85.8 per cent. of the mortality from heart dis-

eases at all ages; in other words, the disease is largely one of well advanced adult life. In this respect, however, cancer is even more important, for the mortality from malignant disease is 91 per cent. at ages 40 and over, of the mortality from this disease at all ages. In contrast, the proportion is only 37.7 per cent. for pulmonary tuberculosis, and 58 per cent. for lobar pneumonia.

It will also be convenient to compare the mortality rates for different years since 1900, and for different

causes, and in illustration of the comparative importance which should be attached to the apparent increase in diseases of the heart. Table 8 shows, for illustration, that while there has been a considerable decrease in the mortality from pulmonary tuberculosis, and a practically stationary condition in the mortality from pneumonia and violence, deaths from old age and ill-defined causes have very materially decreased, so much so that in the latter case they have practically become quite negligible. The decrease in the mortality in old age is of particular significance in that there is a strong reason for believing that deaths from this group have been largely transferred to the present group of affec-

† Principally dropsy, heart failure, sudden death, etc.

tions of the heart. The increase in the mortality from apoplexy and cerebral softening is probably a more accurate measure of the increasing intensity in life strain, and more so than the corresponding statistics for arterial diseases, embolism and thrombosis combined for the earlier portions of the periods, although for the last seven years of the period under consideration the rate has only increased from 30 per hundred thousand of population in 1910 to 37.8 in 1917.

The same conclusions apply to kidney diseases, which have increased from 91.6 per hundred thousand of

population in 1900 to 119.7 in 1917; but if the increase is considered only for the last seven years, the change is not of very material importance.

The question may here be raised that where so much doubt is cast on the unquestionable increase in cancer frequency, as measured by a change in the rate of incidence from 63.8 in 1900 to 94.5 per hundred thousand of population in 1917, why the much more startling and certainly extremely doubtful apparent increase in the mortality from heart disease should go unchallenged. The apparent increase in diseases of the kidneys is largely accounted for by the transfer of deaths from dropsy and the urinary and circulatory systems or groups.

Much interest attaches to the relative frequency of heart affections among the white and colored populations on account of disparity in the rates, of which no satisfactory explanation has thus far been forthcoming. For the registration area, 1914-1917, the information is shown in Table 9 that all heart affections, ages 40 and over, cause a rate of 536.2 per hundred thousand for the white population, against 672.4 for the colored. There can be no question, however, that the difference in the racial incidence of heart affections is real and not apparent. Numerous other investigations, including hospital experience, seem to sustain the point of view that the negro is more liable to this group of diseases, particularly to acute endocarditis, than is the white man. Since accurate diagnosis is more difficult in this case than in many other heart affections, it would seem a foregone conclusion that the higher rate of incidence is real, and for all practical

purposes a racial trait not explained on account of our present ignorance of the almost unexplored field of race pathology. The very much higher rate of incidence from angina pectoris in the case of the white population is also very suggestive, and is not explained by the possibility of erroneous diagnosis or death classification; for the rate for the white population is 28.3 per hundred thousand population at ages 40 and over, against only 13.5 for the colored. In other words, while the mortality from pericarditis is 107 per cent., in the case of the colored race, in excess of the normal

rate for the white race, the mortality from angina pectoris is only 48 per cent. of the corresponding rate for the white population.

Much has been made of the alleged decrease in heart affections in England and on the continent, and the alleged increase in this country. The facts are quite to the contrary, at least as regards England and Wales, to which the present comparison is limited. Table 10

* Rate per thousand.

† Based on civil population only. Years 1915 and 1917 are not strictly comparable with previous years or with United States data.

shows conclusively that heart diseases have apparently increased in England and Wales from 147.9 per hundred thousand of population in 1900 to 172.1 in 1915, the later figures being less useful on account of the effect of the war. Equally suggestive is the apparent increase in deaths from apoplexy and diseases of the blood vessels from 87.1 per hundred thousand in 1900 to 118.0 in 1915. It is to be observed that the decline in the deaths from old age is less marked in England and Wales, although suggestive, being 98.3 per hundred thousand of population in 1900, but only 88.8 in 1917.

International vital statistics require to be used for comparative purposes with extreme caution. Few are in a position to make sure of the comparability of the data without personal inquiry in different countries and personal interviews with registration officials, practicing physicians, teachers of pathology, and the like. There is unquestionably a difference in point of view in the medical practice of America and England which cannot properly be ignored. Such statistics as are available can be relied on only in the most general way; no far-reaching conclusions can be adopted unless based on a painstaking inquiry into the actual facts, and we should not blindly accept mere statistical information, which may or may not be conclusive.

APPLICATION OF FINDINGS TO PRACTICE OF MEDICINE

The subject is entirely too large and too involved to admit of being briefly considered for the practical purpose of rendering substantial aid to the practitioner or the student of clinical medicine. From a life insurance point of view there is hardly a more important group of affections than diseases of the heart, than which probably no other is more typical of what is summed up in the term "adverse selection." As emphasized, however, by Sir James Mackenzie, we are very far indeed from having attained to a position in which the medical judgment, arrived at as the result of even the most thorough examination, can be relied on with absolute certainty in a considerable proportion

of borderland cases. Such attempts as have been made to reduce the experience which has been had to a statistical basis indicate, however, the far-reaching possibilities of really qualified research. The medico-actuarial mortality investigation, for illustration, considered the effect of an irregular pulse, of an intermittent pulse, of a pulse rate of from 90 to 100, and of a pulse rate over 100, on the subsequent expectation of life, with results which may safely be accepted at least as approximately conclusive, although the experience was not sufficiently large to be considered as final.

In the case of applicants with an irregular pulse, the ratio of actual to expected deaths was 95 per cent., but in this connection it is said in the report that:

The low mortality is probably due to the inclusion of many cases where an irregular pulse was found on only one out of two or more examinations. Several of the companies whose experience comprised the largest part of the data were asked to investigate their cases, and it was found that the number with a persistently irregular pulse was small, the abnormality having been found in the first, but not in subsequent examinations. The committee was shown the experience of a company on a group of risks with persistently irregular or intermittent pulse, insured on substandard plans. There were about 120 deaths and the mortality was more than 50 per cent. in excess of the normal. The experience did not show separately the results of irregular pulse and intermittent pulse. Cases in which either of these conditions was found in only one out of two or more examinations were not included.

In further explanation, it is pointed out that in this class "there were undoubtedly many cases in which the condition was merely temporary, due frequently to excitement under examination; while in the substandard group of the company whose experience has been mentioned, the condition was apparently permanent." It is therefore made clear that the statistical results of the investigation cannot be relied on as entirely conclusive, for it is pointed out that the death rate from heart disease in the group considered "was distinctly heavier than the normal." Among applicants with an intermittent pulse at the time of entry into insurance, the ratio of actual to expected deaths was 113 per cent. It is explained in the report that the previous comments apply to this class also, an investigation having shown that in the great majority of cases the intermittent pulse was found on only one out of several examinations.

The death rate from heart diseases in this group was, however, "markedly higher than the normal." It is therefore safe to assume that a persistent irregular and intermittent pulse, determined by precise methods of examination, are symptoms of considerable diagnostic value.

Applicants with a pulse rate of from 90 to 100 experienced a ratio of actual to expected deaths of 172 per cent. In this group the death rate "from heart disease and pneumonia, and especially from tuberculosis of the lungs, was distinctly above the standard." The experience, which is based on 332 deaths, would seem to suggest that a high pulse rate is decidedly more indicative of a physical impairment than an irregular or intermittent pulse.

Applicants with a pulse rate over 100 represent a rather small group of individuals, no doubt on account of the attitude of the companies to reject most of such applicants unconditionally. The ratio of actual to expected mortality among this group was 205 per cent. The explanation concerning the mortality of

this group of causes is, unfortunately, not sufficient for practical purposes. It is one of the lamentable defects of the medico-actuarial mortality investigation that the causes of death, in their relation to impairment, were considered only in a fragmentary manner, and not systematically presented for the larger purposes of clinical medicine.

The foregoing observations are, therefore, suggestive rather than conclusive. I have on more than one occasion suggested the urgency of a dual classification of deaths, known as the Budapest system, which would permit of a more precise judgment than is possible at present. To group the mortality from heart diseases, or the existence of impairments, without reference to secondary causes, frequently classed as primary, must needs lead to much confusion. To classify heart diseases as a group is in itself as misleading as the old classification of "fevers" and the modern classification of "malignant tumors," without reference to the site of the organ affected. Such affections as aneurysm of the valves, atrophy of the heart, displacement of the heart, fibroid disease of the heart, thrombosis or mitral stenosis are all indications of the serious limitations of the present method of a crude classification. Any one familiar with medical nomenclature is aware of the practical difficulties of a trustworthy and strictly comparable classification, even in the easily diagnosed case of valvular disease of the heart complicated by Bright's disease, or pericarditis complicated by some infectious disease of early childhood. There is, therefore, urgent need for an improvement in the statistical treatment of heart affections and in amplification of the death certificate, which should be made to include a few descriptive remarks to facilitate accuracy and uniformity in statistical analysis.

As an illustration of the foregoing, reference may be made to the etiology of pericarditis as presented by Dr. Robert B. Preble² in 1901. Dr. Preble, after pointing out that primary cases of acute pericarditis may clinically occur, although they are extremely rare, states that diseases in which "pericarditis appears as a complication are, in order of their frequency: pneumonia, 34 per cent.; rheumatism, 28.36 per cent.; chronic diffuse nephritis, 11.2 per cent.; tuberculosis, 10 per cent.; sepsis, 4.7 per cent.; aneurysm, 2.6 per cent., and typhoid, 1.7 per cent." He holds that the more extensive the pneumonia the greater the danger of this complication, but at the same time emphasizes the statistical difficulty of exact classification; for the mortality from pneumonia with pericarditis, according to Dr. Preble, is 92.4 per cent. Furthermore, pericarditis appears as a complication of all forms of nephritis, but particularly the chronic diffuse nephritis with contraction.

Reference may also be made here to a valuable paper on the four common types of heart disease, by Dr. Richard C. Cabot,³ in 1914. The discussion is based on an analysis of 600 hospital cases of "failing heart," found to group themselves (1) as rheumatic, (2) nephritic, (3) arteriosclerotic and (4) syphilitic. These four types represent 93 per cent. of the total, the remainder being affected by either goiter or doubtful conditions.

The obvious purpose of all statistical inquiries into the mortality from heart affections is to aid early diag-

2. Preble, R. B.: *Etiology of Pericarditis*, J. A. M. A. 37:1510 (Dec. 7) 1901.

3. Cabot R. C.: *The Four Common Types of Heart Disease*, J. A. M. A. 63:1461 (Oct. 24) 1914.

nosis and disease prevention. Whether or not heart affections are on the increase is quite secondary to the truth, which is not in controversy, that there is an immense mortality from these diseases in comparatively early adult life, which, in the light of modern knowledge, lies unquestionably within the domain of prevention and relief. It has been said in this connection⁴ that "greater accuracy of diagnosis and better statistics will hardly account for the remarkable increase in recent years in the percentage of deaths from heart disorders." The value of a periodic medical examination is therefore urged, and it is said that "the recognition of the signs and symptoms of decompensation seldom fails"; further:

The routine examination of the heart at this stage may show some well marked valvular or other lesion, but there will often be found only such signs as a hasty examination is most apt to overlook. These may be merely a change in the quality of the first sound with a slight increase in cardiac dullness, or there may be associated an irregular pulse volume. Always in this field symptoms should receive equal or greater weight than physical signs.

Finally, the suggestive observation is made, which is fully sustained by every statistical inquiry into the subject, that "it is not the too often impossible *early* diagnosis of cardiac disease which is to be emphasized, but the *earlier* diagnosis."

As I have had occasion to say before, heart affections are of the first importance to life insurance companies. Much progress has been made during recent years which gives the assurance that examinations are made today with a much higher degree of accuracy and thoroughness than in former years. An illustration of the scientific aspects of this question is the recent discussion on "Heart Murmurs—Their Influence on Mortality," by Dr. Oscar H. Rogers and Mr. Arthur Hunter, before the Actuarial Society of America. This paper is an admirable contribution to a very limited literature, which it is hoped will be enlarged by the research work of institutions which recognize the urgency of more qualified consideration. The paper brings out the fact that applicants with mitral regurgitation without hypertrophy experience a mortality ratio of actual to expected deaths of 181 per cent. Among this class, persons underweight experience a mortality of 166 per cent. and persons overweight, of 209 per cent. Applicants affected with mitral regurgitation with hypertrophy experience a ratio of actual to expected mortality of 225 per cent. The importance of hypertrophy is emphasized by selected cases of mitral regurgitation with a history of inflammatory rheumatism, according to which applicants with little or no hypertrophy experience a ratio of actual to expected mortality of 299 per cent., whereas applicants with moderate hypertrophy experience a ratio of actual to expected mortality of 455 per cent.

The group of risks with aortic obstruction was, unfortunately, rather too small for entirely trustworthy conclusions. The ratio of actual to expected deaths among applicants with aortic obstruction without hypertrophy and with minor impairments was 179 per cent. Out of 227 deaths among this class, seventy-three, or 32 per cent., were from heart disease.

Applicants with functional heart murmurs also represent a relatively small group of risks, so that conclusions must be accepted with reserve; but the ratio of

actual to expected deaths in this class was 114 per cent. The foregoing illustrations will serve the purpose of emphasizing the practical value in prognosis of statistical research practically limited to life insurance experience. I cannot do better than to restate the conclusions of Rogers and Hunter, which are deserving of most careful consideration:

Functional heart murmurs, if carefully selected, are insurable among young applicants at standard rates; among applicants over 40 years of age, at rates calculated to provide for a substantial extra mortality.

Mitral regurgitation, if carefully selected, may be insured on terms to provide for a mortality of from 150 to 250 per cent., ratings above 170 to depend on the degree of hypertrophy present in each case.

Aortic obstruction is probably 25 points less favorable than mitral regurgitation.

Hypertrophy of the heart, occurring in connection with heart murmurs, constitutes an additional impairment, and only moderate degrees of hypertrophy are insurable.

Irregular or intermittent pulse increases the hazard of heart murmurs, and if more than slight, the combination results in a very high mortality.

A heart murmur with a history of acute articular rheumatism is a very serious impairment.

COLLATERAL CAUSES OF DEATH

A qualified analysis of the mortality from diseases of the heart should include the collateral or subsidiary causes of death. This is possible only under the so-called Budapest system of dual death classification, which at present is not followed by a single registration department of this country. Some years ago, when I had occasion to discuss this question, I had an analysis made of the male mortality of the Prudential Insurance Company of America for the year 1909, limited, however, to only 2,686 deaths from diseases of the heart precisely registered as such, while in addition there were 1,855 deaths registered as due to other causes in which diseases of the heart were taken note of as a secondary or supplementary cause, disregarded for statistical purposes. There were, therefore, 4,541 deaths in which an impairment of the heart function contributed directly or indirectly to the death of the deceased. If this analysis is extended to all the different registered causes of death, some extremely interesting conclusions can be advanced which must unquestionably be of clinical, or at least prognostic, value. Thus, for illustration, there were 871 deaths from acute nephritis in this experience, of which 222, or 25.5 per cent., were complicated by diseases of the heart. There were 1,945 deaths from Bright's disease, of which 279, or 14.3 per cent., were complicated by heart diseases. In the aggregate ordinary male mortality experience of this company, out of 33,992 deaths, there were 20,547, or 60.4 per cent., without complications, while there were 1,855 deaths, or 5.5 per cent. of the total, complicated by diseases of the heart but in which cases heart disease was not specifically assigned as the immediate cause of death. It is the practice of the Prudential to classify all deaths in which both heart and Bright's diseases are stated on the death certificate under the latter term. It is, therefore, self-evident that unless these facts are taken into account, erroneous conclusions are unavoidable.

CONCLUSION

I may say that of 8,408 deaths of males, 1,811, or 21.5 per cent., were complicated by diseases of the heart; and by specific impairments, 531 cases were

4. The Early Recognition of Heart Disease, J. A. M. A. 66:1025 (April 1) 1916.

complications of valvular disease; 347 cases, of endocarditis; 339 cases, of myocarditis; 215 cases, of organic diseases of the heart not otherwise specified, and 169 cases, of cardiac asthma and dilatation, etc. In the same experience there were 390 deaths from Bright's disease complicated by arterial diseases, principally cerebral apoplexy, from which there were 307 deaths; and arteriosclerosis, from which there were seventy-three deaths.

The foregoing statement must be sufficient for the present purpose to emphasize the extreme importance of a complete collateral analysis of all the causes of death in any discussion of heart impairments, with particular reference to the question of a possible increase in the observed degree of relative frequency. To those who wish to pursue this question further, it may be suggested that the statistics of the Roosevelt Hospital are of particular value in this connection in that they are available for a period of more than twenty years, and so stated as to emphasize the relative importance of complications, or collateral impairments, as the case may be.

ROENTGENOLOGY OF TUBERCULOUS ENTEROCOLITIS*

R. D. CARMAN, M.D.

ROCHESTER, MINN.

The early symptoms of ulcerative tuberculous colitis are not sufficiently characteristic to make possible a definite clinical diagnosis, even in the presence of pulmonary tuberculosis. If any benefit is to come from treatment, it is imperative that the disease be recognized early, and for this recognition the roentgen ray furnishes the most certain means as yet available. A positive and independent roentgen diagnosis of tuberculous colitis is difficult, however, for there are no pathognomonic roentgen signs, as the filling defect and the absence of the normal barium shadow in the cecocolon are signs of any ulcerative lesion. Even the finding of *Bacillus tuberculosis* in the stool is of no value in determining the nature of the lesion in the intestine unless a tuberculous lesion in the lungs or *Bacillus tuberculosis* in the sputum can be excluded. Every patient with indefinite abdominal complaint should, therefore, have a complete roentgenologic and general clinical examination. Tuberculosis has such a predilection for the ileocecal coil that a lesion in this part of the intestine, especially if associated with pulmonary tuberculosis, is most likely tuberculosis. Distal segments of the colon are seldom invaded; the disease almost always involves the proximal portion, especially the small bowel, ileocecal valve, cecum, appendix, and ascending colon (Brunner¹). Necropsies have demonstrated that from 70 to 90 per cent. of persons suffering with advanced pulmonary tuberculosis have tuberculosis of the intestine.

In reviewing the physiology of the colon, the following facts should be kept in mind for a better understanding of the abnormal colon: The cecum and ascending colon form a pouchlike expansion of the proximal part of the large bowel. Their walls are thinnest and therefore weakest, and capable of great distention. The interior depressions of the cecum

correspond with the surface haustra. It is definitely known that food remains in this portion of the colon longer than in any other, and it is thought that this delay is largely due to haustration and antiperistalsis. With these physiologic functions in mind, it is not difficult to understand how their loss by disease explains the emptiness and gap in the physiologic barium shadow seen in ulcerative diseases of the colon. The bowel contents pass with abnormal rapidity, because the normal functions which retard the physiologic progress are absent.

PATHOLOGY OF TUBERCULOSIS OF THE INTESTINE

The pathology of tuberculosis of the intestine may conveniently be divided into three types: (1) nodular; (2) ulcerative, and (3) fibrous.

In the nodular type the lesion is made up of conglomerate tubercles which are principally extraluminal in their earliest stages. The nodules are not infrequently seen alone, apparently unaccompanied by tuberculosis elsewhere; they may rarely be seen in association with chronic ulcerative tuberculous ileocolitis, and in such case may be the sequel of pulmonary tuberculosis. This type can hardly be recognized roentgenologically unless it produces obstruction or encroaches on the lumen of the bowel.

The ulcerative type is frequently associated with the nodular, but in a typical instance ulcerative tuberculous colitis is the primary lesion. However, it is possible for tuberculosis to be associated with it in other parts of the body. This type is evidenced by irregularity of bowel contour in the roentgenogram; in the terminal stages it produces obstruction.

The fibrous or hypertrophic type of tuberculosis is manifested by a marked increase of fibrous connective tissue; the tubercles are discrete and relatively sparse. The large amount of fibrous tissue indicates a marked resistance on the part of the patient. It is the terminal stage of healing tuberculous colitis and pericolicitis. This type gives practically the same roentgen picture as the ulcerative.

TECHNIC OF EXAMINATION

The technic of the examination is not difficult. In fact, it is the same as is used for all other diseases of the intestine. In the Mayo Clinic the enema is ordinarily employed; when necessary, the ingested meal is used; in a few cases both methods may be necessary. The enema is preferable since it demonstrates small irregularities of contour by actually outlining the bowel wall, whereas the ingested meal is so unevenly distributed throughout the normal bowel that its irregularity cannot be distinguished from that due to disease. This is especially true in cases in which there is little involvement. If the enema is employed, the colon is filled under observation up to and including the cecum. If the ingested meal is given, observations with the screen are made at intervals from the sixth to the eighteenth hour. Roentgenograms are made as a matter of record and for study.

ROENTGENOLOGIC SIGNS OF TUBERCULOUS COLITIS

The roentgenologic signs of tuberculous colitis are: (1) filling defects; (2) spastic phenomena, and (3) obstruction.

The first and most important roentgenologic sign of tuberculous ileocecal colitis is the filling defect, which is due to the ravages of the disease plus spastic manifestations. It is best seen during the screen

*From the Section on Roentgenology, Mayo Clinic.

* Presented before the Omaha Roentgen Society, March 27, 1920.

1. Brunner, C.: *Tuberculose, Aktinomykose, Syphilis des Magen-Darmkanals*, Stuttgart, Enke, 1907, p. 399.

examination with the opaque enema. Under pressure of the enema, the cecum and ascending colon are seen to fill irregularly and are decidedly narrowed in their transverse diameter. The normal haustral markings are absent, and Bauhin's valve is usually incompetent. After the pressure of the enema is relieved by shutting off the flow, the involved area usually empties and remains emptied, while the remainder of the colon may retain the enema for some time.

The filling defect and the localized absence of barium shadow in the cecum and ascending colon are not entirely characteristic of tuberculous colitis; I have seen them in ulcerative carcinoma of the cecum and chronic ulcerative colitis. Stierlin² has reported a case of carcinoma in the ileocecal coil with similar findings. Nevertheless, a lesion of the cecum and ascending colon without the physiologic barium shadow should always suggest the possibility of tuberculosis, and tuberculosis should be looked for in other parts of the body, particularly the lungs. If tuberculosis can be definitely demonstrated in the lungs, the lesion of the cecocolon, whether there is an absence of the physiologic barium shadow or not, is most likely tuberculous colitis.

Hypermotility has been emphasized by Brown and Sampson³ as an important roentgenologic sign of tuberculous colitis. The term hypermotility can hardly be applied to this phenomenon because, strictly speaking, hypermotility refers to the passage of bowel contents, at an increased rate, along the entire alimentary canal. Hypermotility in our cases was usually due to diarrhea or achylia, and was of no more value as a diagnostic sign than a six-hour retention in the stomach would be. The gap in the barium shadow, I believe, does not represent hypermotility, but is the effect of diffuse infiltration of the bowel wall which produces rigidity of the part of the intestine affected. It is apparent from this that the physiologic functions of the diseased segment of the colon have been lost and the barium passes through it without hindrance, just as it does through a stomach diffusely infiltrated with cancer. In the absence of diffuse infiltration, spasm stiffens the walls, giving the same motoric effect.

Béclère and Mériel⁴ state that an ulcerated mucosa manifests its irritability by an exaggeration of muscular peristalsis with an abnormally rapid progress of the contents of the intestine. I have never observed this muscular peristalsis, but I have seen marked spasm of the musculature of the colon due to irritability from an ulcerated mucosa, and I am inclined to think that Béclère meant spasm when he said peristalsis. Stierlin is evidently of the same opinion, for in discussing the same subject he mentions no acceleration of motility. Indeed, it has been demonstrated in operations, when the patient is under the influence of narcosis, that this spasmodic condition does exist and its extent is in proportion to the extent of the lesion. For example, if a solitary lesion is present, the spasm is localized and analogous to that seen in gastric ulcer. In this early stage of the disease usually there is no gap in the barium shadow of the ingested meal, but the irregularity of contour due to spasm may be visualized by the opaque enema even if the lesion is not demonstrable.

Stierlin, in 1911, first pointed out the absence of a physiologic barium shadow in the cecum and ascending colon in tuberculosis of the ileocecal coil. Much to his surprise, at a time when normally he expected to show the cecum and ascending colon in the roentgenogram, no shadow was visible; in its advance the shadow seemed to skip the cecum and the ascending colon. In this country Pirie⁵ was the first to notice this phenomenon. By observations at half-hour intervals, continued for from four to twelve hours, he was able to prove that the tuberculous cecum does not retain the barium which normally accumulates there.

Spasm is a manifestation which, to a greater or less degree, accompanies many if not all gastro-intestinal lesions. It is one of the most perplexing conditions with which the roentgenologist has to deal. For instance, lesions so slight as to cause no irregularity of contour demonstrable in the roentgenogram may exhibit marked deformity and narrowing due to spasm. Indeed, the absence of barium from an involved area of the bowel is caused usually by spasm and infiltration of the intestine rather than by hypermotility. This type of spasm is intrinsic in origin and constant in situation; it is present at a second examination and cannot be effaced by antispasmodics.

In our cases, tuberculosis has been more frequent in the small than in the large bowel. The lesions are seen most often in the ileum and the jejunum, but the latter is less frequently affected. They occur in the bowel anywhere from a few inches to 1 foot or more apart and usually become confluent near the ileocecal valve. The affected areas are not more than one-half to three-quarters inch in width. They are slightly elevated, may or may not be studded with tubercles, and involve the entire circumference of the intestine. Palpation of the areas reveals the presence of ulcers in the mucosa.

The roentgen diagnosis of tuberculous enteritis is less certain than that of tuberculous colitis. This is probably due to the physiologic and anatomic difference between the small and the large intestine. The obstruction which is occasionally noted is not characteristic, for it is observed in other pathologic conditions. However, I have observed another sign which may have diagnostic value, namely, delay with irregular filling and segmentation of the small bowel; but further study will be necessary to establish this fact.

SUMMARY

A lesion roentgenologically demonstrated in the ileocecal coil, with irregularity of bowel contour and without the physiologic barium shadow in the cecocolon, although it may represent any ulcerative process, is probably tuberculous if pulmonary tuberculosis is present.

The tuberculous lesions may be nodular, ulcerative or fibrous. They are usually associated to a greater or less extent, dependent on the stage of the disease. The nodular type is recognized by means of the roentgen ray only if it encroaches on the lumen of the bowel, and the ulcerative and fibrous types by irregularity of contour, and in the terminal stages by obstruction.

The presence of spasm must not be overlooked, since it often causes irregularity of contour and is diagnostic even when the lesion itself is not demonstrable.

The opaque enema generally is preferable to the ingested meal in demonstrating the filling defect and spastic phenomena which are roentgenologic signs of tuberculous colitis. A gap in the physiologic barium shadow of the cecocolon in the more advanced cases is demonstrated by the ingested meal, but unquestionably the disease will be demonstrated earlier by the enema.

THE DIAGNOSIS OF EPIDEMIC ENCEPHALITIS

VALUE OF NASOPHARYNGEAL WASHINGS AND OF CEREBROSPINAL FLUIDS *

LEO LOEWE, M.D.
AND
ISRAEL STRAUSS, M.D.
NEW YORK

During the course of investigations carried on within the past year, Strauss, Hirshfeld and Loewe,¹ and Loewe, Hirshfeld and Strauss² established the fact that epidemic encephalitis was due to a filtrable virus. The successful cultivation of this filtrable virus was reported by us.³ The experimental work embodied in these reports demonstrated the close relationship of the virus and the micro-organism to the nasopharynx. Berkefeld filtrates of nasopharyngeal mucous membrane from fatal cases of epidemic encephalitis, and cultures of these filtrates when injected intracranially into monkeys and rabbits, produced the typical clinical and pathologic pictures of the disease. In view of these findings we were led to investigate, by animal inoculation and cultural studies, the nasopharyngeal washings and the cerebrospinal fluids of patients suffering from epidemic encephalitis. In this communication we desire to report our results and to point out their value in diagnosis.

Material from the nasopharynx was obtained by means of nasal irrigation with physiologic sodium chlorid solution, pharyngeal swabs, or the West tube. We have never seen any ill effects from any of these procedures. Nasal washings were filtered directly, unless the presence of an excessive amount of mucus made it necessary to shake the washings with glass beads. For the most part pharyngeal swabs were used, the swabs being carried as high up in the nasopharynx as possible and strong pressure exerted. The pharyngeal swabs were washed in several changes of saline solution, small quantities being used in order to procure a maximum concentration. The slightly turbid fluid so obtained was then filtered. In one case the thick, tenacious, mucopurulent nasal discharge was finely emulsified by grinding in a mortar with sand and physiologic sodium chlorid solution and then submitted to filtration. The filters used in the work were the standard 5 N or W. Berkefeld or Mandler filters, which we had found perfectly satisfactory as regards their ability to hold back the usual test organisms. All filtrates before being used were cultivated on ordinary laboratory mediums to insure sterility.

Our first nasal washing was injected intracerebrally into a *Macacus rhesus* monkey. Subsequently we con-

finied our work to the intracranial inoculations in rabbits and to cultivating in kidney tissue-ascitic fluid medium. From two to four medium or full-sized rabbits were thus inoculated intracranially with each filtrate:

The hair over the left half of the skull was first removed and iodine applied. The head was steadied with the left hand, the body and legs being held by the assistant. With experience, it was possible to dispense with the aid of the assistant. The skull of a rabbit is so thin in certain areas that it can be pierced without trephining. With the exertion of moderate pressure and with a boring movement, the needle with stylet in place was inserted perpendicularly to the lateral surface of the skull at a point 0.5 cm. behind and on a level with the upper margin of the orbit. Three c.c. hypodermic syringes with small bevel, so-called deep injection, needles of from 18 to 20 gage were found best adapted for this work. Throughout the entire procedure, strict asepsis was observed. The amount of filtrate varied; as a rule no difficulty was experienced in injecting 1 c.c., if done slowly.

Rabbits that succumbed were examined postmortem, an attempt being made to remove the brain in sterile fashion. Blocks of brain were taken in sterile physiologic sodium chlorid solution and in 50 per cent. glycerin for cultural study. The remainder of the brain was placed in 10 per cent. dilution of liquor formaldehydi for section. The sections were embedded in paraffin and stained with hematoxylin and eosin.

Cultural studies were carried out with the original filtrates and with the brains of animals injected with these filtrates. Filtrates of brains were mainly used, owing to the difficulty of obtaining the brains uncontaminated. All filtrates were inoculated in amounts of from 0.25 to 0.5 c.c. into a series of tubes containing the ascitic fluid-kidney tissue medium. The tubes were sealed with petrolatum to establish a more perfect anaerobiosis, and were then incubated at 37 C. The positive growths were evident in from five to seven days. In a few instances, rabbits were injected intracranially with these cultures to establish their virulence.

Cerebrospinal fluids removed from patients under sterile precautions were similarly subjected to culture and animal inoculation. The fluids were cultivated in amounts from 0.5 to 1 c.c. The larger amount, when injected intracranially into rabbits, proved to be too toxic, the animals succumbing rapidly without definite pathologic lesions being present. When the dose was reduced, the more typical pathologic lesions were produced. Several times, in order to determine their pathogenicity, the organisms isolated from the spinal fluids, and those recovered from the brains of the animals examined postmortem were reinoculated into animals.

RESULTS

Two c.c. of a filtrate of the nasopharyngeal washings, containing thick mucopurulent discharge, from an epidemic encephalitis patient, were injected subdurally into a *Macacus rhesus* monkey. One week later the animal developed apathy, elevation of temperature, and paresis of both hind extremities. This condition persisted for eight days and then gradually disappeared. Lumbar puncture on the sixth day of the illness revealed clear fluid under increased pressure. There were 16 cells per cubic millimeter, mostly lymphocytes.

The nasopharyngeal washings from fourteen other patients with epidemic encephalitis were injected into a

total of thirty rabbits. Twenty-five of these animals were examined postmortem, fourteen showing the characteristic lesions to a greater or lesser extent. The lesions consisted of meningitis with round cell infiltration, perivascular and adventitial infiltration with mononuclear cells, focal infiltration with round cells, punctate hemorrhages and edema. These lesions were present singly, but most often combined. It required from one to fifteen days for the animals to succumb. Nine of the fourteen rabbits showing lesions were dead within four days. The short period usually

discharged cured. In another case, Dr. Emanuel Libman made a diagnosis of encephalitis lethargica in a woman who was supposed to be suffering from toxemia of pregnancy, for which a therapeutic abortion had been performed. Washings from the nasopharynx were submitted to us for animal inoculation. Two animals injected with the filtrate of these washings died, one in twenty-four hours, and the other in four days. Microscopic examination of these brains demonstrated the characteristic lesions in both. The woman made a good recovery.

* Hemorrhagic spinal fluid. Lesions in animals tend toward hemorrhagic coephalitis type.

required enhances the value of the test. The diagnosis was confirmed by animal inoculations in eleven of the fourteen nasopharyngeal washings tested, or 78 per cent.

The method was of distinct practical value in two instances. In one case, in the presence of a markedly bloody spinal tap, a differential diagnosis had to be made between intraventricular hemorrhage, cerebral neoplasm, cerebrospinal syphilis, and epidemic encephalitis. The symptoms and physical findings did not warrant making a definite diagnosis. One of the two animals injected with the filtrate of the nasopharyngeal washings of this patient succumbed within two days with the characteristic brain lesions. This patient subsequently ran the typical course of the disease, and was

Filtrates of nasopharyngeal washings from seventeen patients with epidemic encephalitis were cultivated on the kidney-ascitic fluid medium, with positive findings in eleven cases. Subcultures of many of these strains were taken successfully and carried along through several generations. In five instances the organism was recovered from the brains of animals injected with the virus of these nasal washings, and in three instances, from the brains of rabbits injected with the organisms isolated from these nasopharyngeal washings.

Cerebrospinal fluids, drawn in sterile fashion from sixteen patients having epidemic encephalitis, were injected intracranially into rabbits in amounts of from 0.25 to 1 c.c. Fifteen of the twenty-nine rabbits that died showed the characteristic microscopic lesions.

Eleven of these animals succumbed within four days, three within six days, and one, eight days after the inoculation. Animal inoculation, therefore, served to confirm the diagnosis in twelve of the sixteen cases tested, or 75 per cent.

Cerebrospinal fluids have yielded the filtrable micro-organism in eleven of the twenty spinal fluids cultivated. It was found in one case on direct smear of the sediment of the centrifugalized spinal fluid. These strains were carried in one instance as far as the eighth generation. The same organism was recovered from the brains of eight rabbits injected with the spinal fluid itself, and from the brains of four rabbits injected with the organism derived from these spinal fluids.

CONTROLS

The filtrate of nasopharyngeal washings from a patient with influenza complicated by bronchopneumonia and sinusitis was injected intracerebrally into a *Macacus cynomolgus*, with entirely negative results.

Filtrates of the nasopharyngeal mucous membrane from six patients dead of diseases other than lethargic encephalitis were used to control our rabbit inoculation experiments. Cases from the surgical wards were preferred, so as to eliminate the possibility of contact with the disease under investigation. Of the fourteen rabbits injected intracranially, only one died, and the brain of this animal had no demonstrable pathologic lesions. Encephalitis could not be produced in six rabbits by the intracranial inoculation of filtrates of nasopharyngeal washings from two patients, one suffering from influenza with bronchopneumonia, and the other from uncomplicated influenza.

Control cultural studies were carried out on the filtrates of seven nasopharyngeal mucous membranes and eight nasopharyngeal washings. This material was obtained postmortem or in vivo from cases other than epidemic encephalitis, with surgical cases preferred. Tissue-ascitic fluid cultures of this material were negative.

Cerebrospinal fluids of four cases (brain abscess, brain tumor, psychasthenia and uremia) were inocu-

lated into nine rabbits in amounts of from 0.25 to 1 c.c. The brains of the two animals that died showed no gross or microscopic lesions.

Cultures were made of the cerebrospinal fluids in seven neurologic cases and one case of uremia with entirely negative results.

CONCLUSIONS

1. The Berkefeld filtrates of nasopharyngeal washings from cases of epidemic encephalitis produce characteristic lesions when injected intracranially into rabbits. This finding has served us as an aid to diagnosis in 78 per cent. of the cases so tested.

2. A minute filtrable organism, identical with that described before by us,³ has been recovered in eleven of the seventeen nasopharyngeal washings cultivated, or 64 per cent.

3. Inoculation of rabbits with the cerebrospinal fluids of patients with epidemic encephalitis confirmed the diagnosis in twelve of the sixteen fluids injected, or 75 per cent.

4. Cultures of cerebrospinal fluids have been positive in ten out of twenty cases, or 50 per cent.

5. Our positive results with cerebrospinal fluid sharply differentiate this disease from poliomyelitis.

6. Our control studies have been uniformly negative.

LIPURIA ASSOCIATED WITH CHRONIC NEPHRITIS *

LOUIS BAUMAN, M.D.

NEW YORK

AND

G. H. HANSMANN, M.D.

IOWA CITY

Almost all of the recorded instances of fat in the urine appear under the caption "chyluria." The several features of this condition which are now more or less well recognized are the occurrence of fat, fibrinogen or fibrin, red and white blood cells in the urine, the direct quantitative relationship between the fat ingested and that excreted in the urine, and lastly, the increase in fat elimination during rest in the recumbent posture. Both the parasitic (filarial) and the nonparasitic forms have been explained by a fistulous communication of the lymphatics with some part of the urinary system. In 1908, Magnus-Levy¹ stated that lipuria could arise only in this manner. Five years later, Sakaguchi² found that the average fat elimination through the urine in health and in a variety of diseases was about 8.5 mg. per day, and that this amount could be increased fourfold by fat ingestion. Only in one case of chronic parenchymatous nephritis did the fat rise to 73 mg. This the author thought was probably due to an altered permeability of the renal tubules. In the course of their work on the behavior of stained fat in the animal organism, Mendel and Daniels³ noted that rats fed on lard stained with sudan III excreted both fat and dye in the urine. Dr. Amy L. Daniels has kindly permitted us to insert two typical protocols of unpublished experiments.

* From the Department of Internal Medicine, State University of Iowa College of Medicine.

2. Sakaguchi, K.: Ztschr. f. physiol. Chem. **48**: 1, 1913.

3. Mendel, L. B., and Daniels, A. L.: J. Biol. Chem. **13**: 71, 1912-1913.

RESULTS OF EXPERIMENTS

Rat 1 received food containing 75 per cent. of lard stained with sudan. The next day the urine was distinctly pink. The residue obtained after evaporation of the ethereal extract was quite pink and contained fat as shown by the melting point and by the odor of acrolein on heating.

Rabbit 4 received 8 c.c. of sudan-stained oil administered by stomach tube. The following day the urine was pink and contained fat, as shown by the melting-point test and by the formation of a grease spot when brought in contact with paper.

More recently the work of Sanes and Kahn⁴ also indicated that an abnormal permeability of the renal capillaries or epithelium might be a factor in the production of lipuria. The data at our disposal appear to support this view. At least, the available evidence makes it probable that there are at least two types of lipuria, the one associated with a fistulous communication, the other entirely due to an abnormal permeability of the renal cells.

REPORT OF CASE

History.—A white farmer (clinical number 4928), aged 37, who had never lived in a tropical region, married, and the father of four children, admitted to the University Hospital, Aug. 2, 1918, admitted a gonorrheal infection about one year previously but denied syphilis, though his wife had had two miscarriages. His family history was not significant. He had undergone two operations: an appendectomy, in 1913, and another operation for peritoneal adhesions one year later. He had also suffered from smallpox and scarlatina. His present illness began in March, 1918, with headache, swelling of the ankles and dyspnea. July 1, 1918, he first noted that his urine appeared cloudy and oily. Physical examination detected an edema of the legs, a hypertrophied heart, and blood pressure of 150 systolic and 100 diastolic. Blood examination revealed a moderate secondary anemia and a strongly positive Wassermann reaction, which was negative on three subsequent occasions after arsenical treatment. The patient was discharged much improved, Sept. 13, 1918, but was readmitted, November 26 of the same year, with headache, generalized edema and fulness of the abdomen. The heart was large, the liver palpable and tender, the blood pressure: systolic, 190, and diastolic, 120. In spite of treatment the headache increased in severity, and the eye grounds, which were normal on the first admission, now showed albuminuric retinitis and retinal hemorrhages. The signs and symptoms of pneumonia developed, and death, which occurred, Dec. 16, 1918, was preceded by vomiting, convulsions and coma.

Urine Examinations.—The urine was always cloudy. Its specific gravity ranged from 1.013 to 1.018. It was neutral or alkaline, and contained much albumin and many casts and occasionally a few red and white blood cells. Fat globules were never present. The renal dietary test (August 6) showed a maximum specific gravity of 1.021, a variation of specific gravity of 17 points. The night urine measured 220 c.c. and had a specific gravity of 1.018. A sample of the turbid urine was evaporated to dryness and extracted with alcohol-ether mixture. The extract was precipitated with acetone. The precipitate gave positive tests for phosphorus and glycerol, thus indicating the presence of lecithin. The filtrate responded to the test for cholesterol.

The influence of fat ingestion on the fat content of the urine was studied by Bloor's method. The results are shown in the accompanying tables.

A second dietary test was performed, December 12. The maximum specific gravity was 1.020, the variation of specific gravity was 12, the night urine measured 950 c.c., and its specific gravity was 1.008. No retention of nitrogen or chlorin was found during a period of five days.

Blood Examinations.—The results are expressed in terms of milligrams per hundred cubic centimeters of blood. Owing to external conditions it was not possible to carry out

all the determinations that we had in mind. August 6 (three hours after the midday meal), the urea-nitrogen content was 37; the uric acid, 3.8; the creatinin, 2; the cholesterol, 180; the glucose, 110; the chlorids, 703; the carbonates, 60 per cent. by volume, and the plasma proteins, 4,440. December 15 (patient in coma), urea nitrogen was 17.8, and the carbonates of the plasma were 44.7 per cent. by volume.

Necropsy Findings (by Dr. Frank Paul).—Each pleural cavity contained about 300 c.c. of yellowish, watery fluid, which coagulated spontaneously. The lower lobes of both lungs showed bronchopneumonia. The heart showed hypertrophy and dilatation, especially of the right side. The aorta was normal throughout. There was no enlargement of the thoracic duct or other lymphatics. The abdomen and its contents were normal except for the kidneys. These measured 13 by 8 by 3 cm. and weighed 215 gm. On section they cut with little or no resistance. The cortex measured 1 cm., was soft, and presented a yellowish, fatlike appearance. The capsules stripped easily. The pelvis contained an unusually large amount of fat. Frozen sections stained with sudan gave negative results. Further microscopic examination of the kidneys disclosed the fact that the tubules in the cortical region were swollen, and that the cells were large, cloudy and granular but not fatty. In some, the lining cells were entirely absent. The glomeruli were enlarged, and many showed an increase in connective tissue but no fatty or amyloid degeneration. A large number were adherent to the capsular wall. The capsules were thickened and very vascular. The capsular epithelium showed proliferation in

certain instances. Areas of round-cell infiltration were present. The medulla was very vascular. The tubules were not as large as in the cortex. Their lining cells were clear. There was a slight increase in connective tissue. Sections of the kidney stained by Levaditi's method for spirochetes were negative. Excepting for a marked degree of endarteritis, microscopic examination of other organs, including the brain, was negative.

COMMENT AND CONCLUSIONS

The clinical, chemical and pathologic data suggest a progressive nephritis, possibly of syphilitic origin, associated with lipuria and terminating in uremia. The lipuria was influenced by the amount of fat in the diet. The absence of coagulated protein, the scarcity or absence of cells in the urine, and the apparent absence of a fistulous communication, indicate that the lipuria was due to an altered permeability of the renal epithelium. The presence of lecithin and cholesterol are worthy of note (though both substances have been found by a number of authors on previous occasions). In this case there was no increase of cholesterol in the blood. The occurrence of typical uremic symptoms without cerebral edema or retention of urea has also been pointed out before. The incidence of syphilis in this case recalls the work of Stengel and Austin,⁵ who noted the frequent occurrence of doubly refractile bodies in the urine in nephritis associated with syphilis.

ACUTE PERFORATION OF MECKEL'S DIVERTICULUM BY FOREIGN BODY (FISH-BONE)

REPORT OF CASE *

FREDERIC HAGLER, M.D.

AND

JOHN W. STEWART, M.D.

Visiting Surgeon and Resident Surgeon, Respectively, St. Louis City Hospital

ST. LOUIS

We have failed to find in the records of the St. Louis City Hospital any case similar to the one reported herewith, which we consider of sufficient interest and rarity to merit detailed mention.

REPORT OF CASE

History.—C. A., white man, aged 39, admitted to the hospital, Feb. 11, 1920, had suffered from abdominal pain for two days prior to admission. At first the pain was generalized, cramplike and intermittent. It was mild in the beginning, and the patient worked as usual on the first day. On the second day, the pain was more severe, confining the patient to bed. He was nauseated, but did not vomit. Late in the day, he had a severe chill. On the day of admission, the pain had become localized to the right lower portion of the abdomen, but was constantly increasing in severity. A self-administered dose of castor oil in the early morning had effected a large bowel movement, but there was no vomiting. Nausea had continued.

Examination.—The patient was well developed and well nourished. The head, neck, chest and extremities were normal. The abdomen was slightly distended; there was distinct muscular rigidity on the right side. Slight tenderness was present in the appendicular region. There was no dullness in the flanks, and no masses were palpable. Tenderness was elicited on the right side by rectal examination. The leukocyte count was 19,600. The systolic blood pressure was 135; diastolic, 80. A diagnosis of acute appendicitis was made, and an operation was performed.

Operation.—Under ether anesthesia the peritoneal cavity was opened by a vertical incision through the right rectus muscle. The appendix was found to be fastened with light adhesions to a large omental mass which lay just below the brim of the pelvis on the right side. After being freed, the appendix was removed in the usual manner. Further exploration revealed a loop of lower ileum, approximately 3 feet from the ileocecal valve, enclosed in the omental mass. When the omentum was separated, a pouchlike structure was found springing from the intestine, and slightly nearer the tip than the base of the pouch was a small perforation through which a stiff, slender sharp-pointed foreign body protruded. Some pus and intestinal contents were present in the omental mass. The mesentery was very edematous and contained a group of greatly enlarged glands. The loop of ileum which had been encased in omentum was cyanotic, lusterless, and apparently hope-

lessly damaged by infection and constriction. Accordingly, about 6 inches of damaged bowel bearing the perforated, pouchlike structure were resected, and end-to-end anastomosis was performed. Exploration revealed no other diverticulum in the small intestine. The incision was then closed in layers without drainage.

Postoperative History.—The first twenty-four hours following operation were normal, but on the second day the abdomen became markedly distended and tender. The pulse was rapid, the temperature elevated, and incessant vomiting developed. The wound was reopened, February 13, at which time a general peritonitis was well established. The intestinal loops were distended, dull red and lusterless. The intestinal wall immediately above and below the site of resection showed some small gangrenous areas, the mesentery showed some thrombosis, and there was some leakage at the line of anastomosis. Several inches of damaged intestine were fastened outside the abdominal cavity (to be opened a few hours later). Drains were placed, and the wound closed loosely. From this time the symptoms of general peritonitis increased steadily in severity. The patient succumbed to this condition, February 17.

Examination of Specimen.—The specimen consisted of a 6-inch section of lower ileum, from which a pouchlike diverticulum sprang, about midway between the mesenteric attachment and the free border. The lumen of the diverticulum was continuous with the lumen of the intestine, but was somewhat less in diameter. The length of the pouch was 3.5 cm., and it ended in a globular extremity. The structure of the wall of the diverticulum was identical with that of the adjacent ileum, and the layers of intestine and diverticulum were directly continuous. Lying within the lumen of the diverticulum was a slender fish-bone, one end of which was firmly impacted in the wall, while the other sharply pointed extremity protruded through a perforation located about halfway between the base and tip.

Microscopic examination of sections from the diverticulum revealed normal intestinal structure modified by inflammatory changes.

The diagnosis was Meckel's diverticulum, with acute perforation due to impacted fish bone.

COMMENT

Through several excellent clinical articles—those of Richter¹ and McDonald² being especially commendable—Meckel's diverticulum has become well recognized as a cause of various surgical lesions. It may cause intestinal obstruction, intussusception and volvulus; it harbors foreign bodies as does the appendix, and may be the seat of acute inflammation and perforation. Its pathology is closely analogous to that of the appendix, and its symptomatology is practically the same. Gebele³ collected the records of four cases of simultaneous acute diverticulitis and acute appendicitis, while Pearce⁴ has added the report

Above, hardened specimen with glass rod in lumen of intestine and fish-bone projecting from perforation in diverticulum; below, opposite side of specimen after removal of the half of diverticulum nearest the camera.

of a case of acute appendicitis with simultaneous acute perforation of Meckel's diverticulum.

Stern⁵ collected records of fifteen cases of acute perforation in 1917, and added two of his own; his list, however, is incomplete and comprises only a fraction of the total number of cases reported. Among the foreign bodies found in Meckel's diverticulum are coproliths, apple seeds, cherry stones, needle, Murphy button (reported by Peck⁶), fish bones, orange peel, ascarides and threadworms. These foreign bodies are usually found incidentally, and are seldom directly responsible for the perforation. We have found reference to only two other cases of perforation due to fish bones.

Aside from mere academic interest in this unusually rare case, we may deduce the practical lesson that if at operation the appendix does not seem sufficiently involved to account for the severity of the symptoms, then Meckel's diverticulum should be borne in mind in searching for the seat of trouble. We incline also to the belief that had we in this particular case instituted early enterostomy and abdominal drainage instead of primary resection, we might have secured a more happy result.

UTERINE RUPTURE AT TERM AFTER PITUITARY EXTRACT

COMPLICATED BY PREMATURE SEPARATION OF THE
PLACENTA *

ALICE F. MAXWELL, M.D.
SAN FRANCISCO

Uterine rupture is one of the most serious complications occurring during pregnancy. It is fortunate that the condition is a rare accident, since the emergency is followed by such high fetal and maternal mortality. Individual reports as to the frequency of the complication vary from one in 250 cases (Taufner) to one in 6,100 cases (Leopold¹). Statistics from the Berlin Frauenklinik (Koblanc²) give a frequency of one in every 462 cases; New York Lying-In Hospital (Lobenstine), seventy five in 60,000 cases, or one in 800; Moscow Maternity (Ivanoff, 1877-1901) one in every 956 cases, or 124 cases in a series of 118,581 confinements. Freund,³ collecting statistics of seventeen investigators, reported a frequency of one in every 2,114 cases; in the Royal Maternity Charity in London for the years 1827-1856, eight cases in a series of 48,996 pregnancies, or one in 6,150 cases. The statistics with few exceptions are taken from hospital reports and do not show the true frequency, since it often occurs that the patient succumbs at once at home, or else survives the immediate shock of an incomplete rupture to die later when the delayed death is incorrectly attributed to peritonitis or some other condition.

Rupture of the uterus may be complete or incomplete, and may occur at any time during pregnancy

or labor. Brandt states that it occurs eight times more frequently in multiparas than in primiparas. Spontaneous rupture during early pregnancy is one of the rarest accidents. Baisch,⁴ in 1903, collected eighteen instances of rupture during pregnancy from scar, trauma, overdistention, or diseases of the chorion. Incarceration and placenta praevia may be determining factors, as illustrated in Arnold Lea's cases in which rupture occurred spontaneously at six months and seven and a half months, respectively. During the puerperium, a dissecting metritis with sloughing may terminate in rupture. Yet the great majority of cases rupture during labor and may either be spontaneous or follow trauma. The predisposing causes are numerous, and much stress is laid on the degenerative changes or weakening of the uterine musculature resulting from tumor growths, overdistention, and the scars from myomectomies, perforations and cesarean section. Frequently, however, microscopic evidence of any degeneration of the myometrium is wanting. Becker has reported an interesting case of repeated spontaneous rupture, and has collected twenty-seven similar cases from the literature. Within recent time the profession has been aroused by the many cases which occur in pregnancies following cesarean section. As early as 1886, Krukenberg⁵ stated that rupture occurred in 50 per cent. of such cases; and even in 1914, Rongy⁶ concluded that 3 per cent. of these women will have a ruptured scar with a 50 per cent. mortality. Prolonged labor following a disproportion between passages and passengers with undue thinning of the lower uterine segment predisposes to rupture. Among the many exciting causes we include uterine manipulation and the untimely use of oxytocics. My purpose in this paper is to report a case of uterine rupture occurring after the use of a small dose of pituitary extract.

Dale,⁷ in 1906, had noticed that pituitary extract caused rhythmic contraction of the nonpregnant uterus. The extract was introduced in obstetrics in 1909 by Bell of the Royal Infirmary of Liverpool to overcome uterine inertia and check the bleeding of placenta praevia and of cesarean section; also by Foges and Hochstaetter of Vienna in the same year. These three investigators began the use of the preparation soon after the announcement of Frankl-Hochwart and Froelich that pituitary extract had a marked stimulating effect on the uterus of a pregnant animal.

Like all powerful physiologic principles that have been introduced in therapeutics, it was enthusiastically accepted as a valuable addition to the obstetric armamentarium. Reports began to appear illustrating its widespread acceptance, before its value, limitation and dosage were determined clinically. The dictum of the manufacturers of the product that "the drug was remarkably free from danger even when given in enormous doses" was accepted. Thus, Edgar,⁸ in 1913, advocated its employment with an incompletely dilated cervix for uterine inertia in doses of from 0.1 to 0.4 gm. Gousew,⁹ in 1913, after using the extract in forty-eight cases, declared that "irregular pelvis not

beyond a medium degree of contraction were no contraindication for its use even when the presenting part stood above the inlet." The employment of pituitary extract in contracted pelves to force the presenting part through the brim and pelvic cavity, and to stimulate labor pains in such malpositions as face and occiput posterior presentations, was not infrequent. It does not excite comment, therefore, that in the light of our knowledge of the powerful stimulating action of the drug, its indiscriminate use was followed by numerous complications. Thus, reports of fetal asphyxia, maternal collapse, tetanus uteri, premature separation of placenta and uterine rupture began to appear, the last resulting in a high mortality for mother and child.

McNeile¹⁰ cites a case and collected statistics of fifteen cases of rupture after pituitary extract with thirteen maternal deaths; Wertebaker¹¹ reported two additional cases of rupture, and numerous isolated reports of the same complication have appeared from time to time in the literature. The usual dosage was 0.1 gm., which was repeated when deemed necessary. On the strength of the many unfavorable reports following the administration of the drug in labor, the initial enthusiasm has been replaced by a more conservative notion as to its field of usefulness, and Norris¹² declares that the "innumerable reports of rapidly and safely terminated labors constitute the real danger of pituitrin." Most obstetricians today are keenly aware that in hypophyseal extract we have a powerful therapeutic principle that can be employed in labor only when certain conditions are fulfilled in the presence of definite indications. Briefly stated, pituitary extract has no place in a normal labor, and its use should be limited to uterine inertia coming on when the head is well engaged without disproportion between the child and the mother's pelvis, with complete dilatation of the cervix, and without undue thinning of the lower uterine

segment. The consensus is that a 1 c.c. ampule equivalent to 0.1 gm. of the drug is too large a dose, and that one half or one third of this amount is within safe limits and may be repeated frequently.¹³

The following case occurred in the obstetric department of the University of California Hospital:

REPORT OF CASE

Mrs. E. C., multipara, aged 44, 5 feet 7 inches in height, whose abdomen at term was not pendulous, and whose pelvis was normal, had had seven spontaneous miscarriages between one and three months, and eight full term pregnancies. She had never been curetted or had had any other gynecologic procedure. Her sixth labor was terminated by a midforceps operation for fetal indications. The fetus weighed 11 pounds.

The seventh labor terminated spontaneously in ten hours, the child weighing 9 pounds. Our interest centers in her eighth full term pregnancy. When the patient was at term she had a sudden hemorrhage without pain. She could not be persuaded to enter the hospital, and refused to report for further examinations and was not seen again until midnight two weeks later, when she entered the hospital. She had been bleeding slightly for a week before entry, and had lost about 200 c.c. a few hours previous to admission. Examination revealed a soft abdomen, left occipito-anterior position, with a floating head. The cervix was undilated, and there were no signs of hemorrhage. The uterus was irritable, and contracted irregularly. One hour after entrance, the membranes ruptured spontaneously. Five hours later, weak pains began. The fetal heart was not heard at any time during the labor. At 9 a. m. the cervix was completely dilated; the head was well fixed. Because of

Incomplete and complete rupture in right uterine segment: normal implantation of placenta; premature detachment 5 cm. in extent.

the good condition of the mother, the absence of fetal heart sounds, and the cessation of all signs of hemorrhage, there was no indication to deliver the patient. One-third c.c. of pituitary extract (pituitrin, B. W. & Co.) was given intramuscularly, and the pains, which had been irregular, became more frequent and stronger. For one and a half hours the advance of the head was slow but steady, and then the pains became very weak and infrequent. The patient's condition at this time was good. With the head at the level of the spines, one-third c.c. of pituitary extract was repeated. Contractions began immediately, but were not

tetanic, yet in a few minutes the patient complained of air hunger, went into extreme shock, and died within a few minutes after the administration of the drug.

At necropsy when the abdomen was opened, there was considerable free blood in the pelvis. There had been retroperitoneal bleeding, which had started in the right broad ligament and had extended along the vertebral column up to the lumbar region. The fundus of the uterus was intact, but the entire lower uterine segment to the right of the midline posteriorly was so thinned that only the peritoneum remained, and the body of the child could be seen through this layer. Here there were two slitlike ruptures of the peritoneum about 4 cm. long.

When the uterus was opened, the placenta was found attached to the fundus, but had separated over an area about 5 cm. in diameter. This condition explained the bleeding during pregnancy. An incomplete rupture was present on the right side, extending into the broad ligament through the uterine vessels. The child was in the left occipito-anterior position, weighed 10 pounds, and its palms and soles showed beginning maceration.

Microscopic examination revealed the typical invasion of the myometrium by blood cells at the site of rupture, but no degeneration of the uterine musculature in the region of the placenta or elsewhere.

COMMENT

There were no predisposing causes of rupture, that is, no cicatrix from previous operative procedures or sepsis, nor prolonged labor, the duration from first pain to time of rupture being less than six hours. Before the necropsy, it had been suggested that the premature separation of the placenta might have led to a weakening of the uterine walls by a diffuse hemorrhagic infiltration of the muscle fibers, but this was not confirmed at postmortem or by subsequent microscopic examination. Moreover, the site of rupture in the lower segment was remote from the placental site, namely, the fundus. Pituitary extract employed in a conservative manner was administered in the presence of well established indications and in doses well within the limits of safety, with disastrous results.

THE TECHNIC OF NERVE SUTURE

BYRON STOOKEY, A.M., M.D.

NEW YORK

In a previous paper,¹ brief consideration of the surgical principles of peripheral nerve injuries as well as a few points of technic were discussed. The importance of the latter would seem to warrant further presentation in greater detail than was possible in the scope of the former article. On the utmost consideration of minute points of technic, more exacting perhaps than in almost any other field of operation, may depend,

Fig. 1.—Lines of incision for exposure of the musculospiral nerve: A, exposure of the upper and middle thirds. The incision begins three finger breadths below the posterior angle of the acromion and is carried directly downward in the long axis of the arm to about the level of the insertion of the deltoid; it then turns abruptly outward to a point about 1 cm. dorsal to the insertion of the deltoid and thence continues directly downward approximately 6 cm. In the middle posterior part, the skin is widely undermined so as to bring in view more of the long head of the triceps. In the upper angle the outer and long heads of the triceps are separated; below, the outer head is split in the direction of its fibers. B, exposure of the middle and lower thirds. The incision begins at about the level of the insertion of the deltoid and on a plane slightly posterior. It is carried directly downward in the long axis of the arm from about 6 to 8 cm. and then passes abruptly anterior to the cleft between the brachialis anticus and the longitudinal fibers of the supinator longus. Both lines are perpendicular except in the lowermost part, whence the line curves slightly anterior into the antecubital fossa. In the upper part of the wound the outer head of the triceps is split in the direction of its fibers, thus exposing the nerve; the nerve is then exposed in the lower angle and traced upward. The outer head of the triceps at this point is tunneled under, and retracted with a band of gauze. Thus the entire nerve from its middle third to its termination in the antecubital fossa is exposed without permanent damage to any of the muscles.

Fig. 2.—The musculospiral nerve has been exposed in its middle and lower thirds by the incisions outlined in Figure 1 (the nerve has been somewhat enlarged out of proportion). A, the long and lateral heads of the triceps have been separated, exposing the musculospiral nerve; a piece of gauze is shown passing beneath the lateral head. B, the nerve has been exposed in the lower third; the lateral head of the triceps is shown tunneled under and retracted by means of a piece of gauze; the gauze retractor stops the hemorrhage from the muscle and serves as an excellent retractor. C, the nerve has been mobilized in both its middle and lower thirds and has been drawn into the anterior part of the wound. The nerve was caught in dense scar; the point of constriction may be noticed; muscular branches are seen which have been freed but carefully safeguarded.

I think that this report should serve to emphasize that:

1. There is danger in the indiscriminate use of hypophysial extract in labor, especially in the doses usually given, namely, 1 c.c. ampules.

2. Even when employed for the strictest indications and in small doses, complications may ensue so rapidly that they cannot be met adequately even in well equipped hospitals.

in large measure, the ultimate results of peripheral nerve surgery.

POSITION OF THE PATIENT

Sheets should be placed so as to permit free movement of the extremity. This is necessary in some cases in efforts to move the limb in order to approximate the nerve ends and also to enable the surgeon to alter the

incision and exposure. As a practical point it will be found helpful to cover the foot and lower limb, not involved in the operative field, with sterile stockinet, and also the forearm in operations on the upper extremity. The hand should be covered when not to be included in the operation with a tight fitting rubber or cotton glove. Both of these coverings fit snugly, permit of accurate observation of individual muscular

Fig. 3.—Exposure of the posterior interosseus nerve: *A*, the brachioradialis and extensor carpi radialis longus and brevis are retracted laterally; the extensor communis digitorum, mesially, exposing beneath the supinator brevis. The fibers of the supinator brevis are separated by blunt dissection in the direction of their course. In this manner the posterior interosseus nerve is readily identified. The forceps are shown passed beneath it. In most incisions an attempt is made to find the nerve at once by cutting through the supinator brevis parallel to the nerve. By so doing, unless the incision is directly over the nerve, frequently most hard to gage, difficulty is encountered in finding the nerve. However, by first splitting the fibers of the supinator longus, which run at right angles to the nerve, the latter is almost instantly found. *B*, the nerve having been identified as described above, the fibers of the supinator brevis are cut following the course of the nerve. The muscle is retracted and the nerve freely exposed to the point at which it breaks off.

movements and palpation of individual tendons during the electrical examination, and also admit of free movements of the extremity without deranging the draping and without loss of time.

MANAGEMENT OF OPERATIVE FIELD

By beginning the incision below and extending it upward, much of the troublesome venous bleeding, due to veins being cut successively as the incision is increased, may be avoided. When possible, the superficial scar should be excised. The skin edges should be well undermined so as to include the fatty fascial layer and to bring the fat with the skin edges into the new line of closure. Unless this is done, the line of union will stretch and a broad scar result. The flaps should be prepared for closure before searching for the nerve, all bleeding points tied, and the undermined edges packed with gauze after making certain that the proper line of closure has been insured. Unless this is done before nerve suture is accomplished, the extra maneuvering, coincident with preparation of the flaps, may derange the delicate line of nerve sutures.

When the deep scar is extensive, it is best to identify the nerve both above and below in normal areas, selecting, if possible, such points within the field as offer anatomic guides to the nerve in question;

for example, the ulnar nerve in the ulnar groove behind the elbow, or its relation to the flexor carpi ulnaris tendon in the forearm, or the median nerve just under the mesial border of the biceps muscle, etc.

In following the nerve from above down and from below up, care must be taken to safeguard the delicate branches to adjacent muscles. This factor, together with the close proximity to large vessels, compels the neurosurgeon to advance slowly and with extreme caution. The nerve may be retracted conveniently by passing moist tapes, about 1 cm. wide, around the nerve, beginning on the side on which there are either large vessels or important branches, so as to avoid including them. The ends of the tapes are clamped with artery forceps, the weight of which may suffice to hold the nerve in any desired position, without injury to the nerve.

While dissecting through the scar, the knife should be changed frequently so as to have at all times one that is sharp. The scar is often penetrated with stray neuraxes which seem to give to nerve scar a denser and harder consistency than is usually found, owing, possibly, to the presence of neurokeratin.

When feasible, the deep scar should be excised. Frequently this is not possible. Instead, after the nerve has been freed, the scar may be infolded on itself and sutured. In this manner a smooth bed may be made, new scar formation avoided and troublesome scar hemorrhage circumvented. When a smooth bed for the nerve cannot thus be made, either a small part of a muscle belly (not a cut and raw muscle surface, for this only increases scar formation) may be sutured so as to form, by its fascial covering, a smooth surface for the nerve; or a fatty flap may be passed around the

Fig. 4.—Incision and exposure of the sciatic nerve in its upper third: *A*, question mark skin incision. It begins above at approximately the level of the posterior inferior spine, extends obliquely downward and outward, about three finger breadths mesial and inferior to the great trochanter. It then curves over the gluteal fold toward the midline of the thigh posteriorly, from which point it may be continued any distance down the thigh. The skin is widely undermined until the insertion of the gluteus maximus is exposed. *B*, exposure of the sciatic nerve from the lower border of the pyriformis to its entrance into the thigh. The gluteus maximus muscle is split in the direction of its fibers, by blunt dissection down to its insertion into the gluteal ridge. The insertion is then cut transversely across, about 2 cm. from the bone, so as to admit of resuture. The whole muscle is then reflected upward and mesially. If the incision is rightly placed, the blood vessels are also reflected upward, consequently with very little attendant bleeding. The nerve may be followed any distance into the thigh by direct prolongation downward of the exposure.

nerve or only under it. A free transplant will tend to form additional scar and should be avoided. Care should be taken to suture the fatty flap to adjacent

tissues on both sides of the nerve in order that constriction about the nerve may be prevented. Generally speaking, if the line of nerve suture has been made so as to obtain epineural approximation, no further protection of the nerve trunk is necessary.

Fig. 5.—Suture of the sciatic nerve and the nerve to the hamstrings. The external and internal divisions have been separated and the scar removed, after which the ends were brought together. The widely separated ends of the small nerve to the hamstrings have been found in the scar, freed and sutured. The upper inset shows the level of the incision; the lower inset, the tissue removed from the external and internal popliteal nerves.

the cotton, they stand out in contrast against the white background, and they remain in place when placed at any given point on the cotton. Furthermore, at the end of the operation the underlying tissues, as a result of being covered constantly with moist cotton, are not traumatized or dried, and appear as fresh as when first incised. When such pads are not used, the threads are often hard to find in the tissues and may become more or less adherent to them.

Constant irrigation is maintained with salt solution, particularly when the nerve ends are cut and during the time they are being sutured. This helps to arrest oozing from the scar tissue and bleeding from the nerve ends, and avoids trauma connected with sponging. If sponges are used, small bits of moist cotton are placed over the nerve ends. If the bleeding is more profuse, bits of torn muscle held over the bleeding points will be found useful.

The nerve being freed, the surgeon should palpate the parts involved as well as the whole nerve trunk exposed in the field.

Operative electrodes are then applied and each stimulus carefully noted by inspection and palpation. Occasionally responses may be appreciated by palpation which might otherwise have passed unnoticed. It must be remembered that even though a negative response results, it cannot always be interpreted to mean that neuraxes have not penetrated the scar and passed into the distal stump. Although having passed the scar, they may not have reached their ultimate destination within the muscle; or, having gained the muscle, they may not yet have formed the motor end plates. Hence a negative response cannot always be held to imply failure in

downgrowth. The whole clinical ensemble as well as the anatomic field must be taken into consideration.

SPECIAL INCISIONS

For musculospiral nerve injuries in the upper and middle thirds, the position and incision described by Stookey and Guild² will be found to facilitate exposure and will also be found to be physiologically economical, in that no muscles are cut transversely, but they are split in the direction of their fibers.

For exposure of the middle and upper thirds, the arm should be placed perpendicular and at right angles to the body, with the forearm flexed over the chest, resting on a folded pillow and held in position by an assistant.

The landmarks for the skin incisions are: above, the posterior angle of the acromion; and below, the tip of the olecranon. The incision begins three finger breadths below the acromion, and continues downward to about the level of the insertion of the deltoid; thence it turns somewhat abruptly outward to a point about 1 cm. dorsal to the insertion of the deltoid, and continues directly downward approximately 6 cm. In the middle posterior part of the incision the skin edges are widely undermined.

In the upper angle of the wound, the posterior border of the deltoid and the long and outer heads of the triceps can be identified. The two heads of the

Fig. 6.—Technic of end-to-end suture: *A*, two catgut stay sutures have been passed on the lateral portions of the nerve, equidistantly placed; the suture below is tied, and the ends are held by a pair of forceps; the suture above shows the direction and depth of the bite; the suture is rather deep, passing between the funiculi, becoming, really an epineural, perineural, epineural suture; this suture is tied in like manner and clamped; these two sutures bring the deeper parts of the nerve together, prevent hemorrhage, and serve as a means of fixation of the nerve. *B*, the two stay sutures are shown in place and the nerve held in position while the fine silk epineural sutures are passed; sufficient sutures are used to insure epineural approximation; the sutures are placed so as to evert the epineural edges when tied. *C*, the anterior part of the nerve having been sutured, the stay sutures are reversed, exposing the under surface for suture; this shows the obvious advantage of the two lateral stay sutures over the single suture. *D*, the suture is here shown completed, the knots tied on one side and the epineural edges everted, insuring smooth epineural contact within.

triceps are separated in their fascial plane, and the incision carried downward through the glistening aponeurosis, beneath which the nerve will be found. The nerve is now traced to the lower angle of the wound. At this point, the nerve will be found passing abruptly toward the anterior part of the arm. The triceps in the anterior part of the incision is now incised perpendicularly in the direction of its fibers. The intervening muscle belly can be tunneled under and a complete exposure of the nerve thus obtained from the lower border of the *teres major* to the junction of the lower and middle thirds, with essentially no permanent damage to any of the muscles.

Fig. 7.—Intraaneural injection of salt solution; internal neurolysis after liberation of both divisions of the sciatic nerve. This patient showed return of function in seven weeks.

For exposure of the middle and lower thirds, the anterior incision described above is carried from the level of the insertion of the deltoid downward for from about 6 to 8 cm.; it then passes abruptly anterior to the cleft between the *brachialis anticus* and the longitudinal fibers of the *supinator longus*, and thence downward, more or less perpendicularly, curving slightly inward to the antecubital fossa. The usual incision for the lower third of the musculospiral nerve is not sufficiently perpendicular and is placed too far anterior, near the belly of the biceps.

For further details and for a description of the exposure of the posterior interosseus nerve, the reader is referred to the original article.

For exposure of the sciatic nerve in its upper third, the incision advocated by Klotz is modified so as to permit one to follow the nerve into the thigh without an additional incision.

The incision begins approximately at the lower inferior spine of the innominate and is carried obliquely downward and out to a point about three finger breadths mesial to the great trochanter, thence curving downward and inward over the gluteal fold to the median line of the thigh posteriorly. The incision is more or less the shape of a question mark. The lower and outer angle of the skin incision is undermined until in line with the attachment of the *gluteus maximus*. This attachment is freely exposed. The deep incision is now made parallel to the fibers of the *gluteus maximus*, separating them in the direction of their course, beginning above at the upper angle of the skin wound and carried directly downward to a point three finger breadths below the great trochanter and thence downward across the insertion of the *gluteus muscle*. The insertion is cut approximately 2 cm. from the bony attachment and the whole muscle reflected toward the median line. If the incision has been correctly placed, the main vessels are reflected upward on the muscle and little bleeding is encountered. The nerve is freely exposed from the lower border of the *pyriformis* to its entrance into the thigh. By means of this skin incision the nerve may be traced any distance farther down the thigh merely by a direct prolongation downward in the midline.

OPERATIONS AVAILABLE

Neurolysis, i. e., liberation of the nerve either with or without intraneural injection of salt solution under pressure so as to perform, as it were, an internal liberation; end-to-end suture, with or without transposition of the nerve; nerve transplantation, either fresh autogenous or homogenous grafts preserved on ice in petrolatum or liquid petrolatum, or nerves preserved in alcohol, are the operations of choice. Nerve crossing, partial or complete, may be of limited value in certain selected cases in which the anatomy may admit of utilizing adjacent nerves. Here obviously only motor nerves having related cortical centers should be employed.

Certain operations are mentioned in order that they may be avoided, since it has been shown that they are of no value and may actually do harm. Nerve flaps, so ardently advocated by Mackenzie of Portland, are worthless, as Huber³ and I⁴ have shown in experimental work and in a critical review of all cases. Huber has also shown that suture à distance offers no practical hope of regeneration. Hofmeister's lateral implantation is also to be avoided.

The value of tubulization has not yet been definitely determined, though Huber's elaborate experiments, nearly concluded, will no doubt admit of their evaluation. He has found that Cargile membrane treated in 95 per cent. and absolute alcohol persists in the tissues for five or six months and causes little or no local reaction, whereas the usual membrane is absorbed within two or three weeks. Huber's Cargile membrane may, therefore, have a particular field of usefulness, not only in nerve surgery, but wherever such membrane is used to prevent adhesions and where it is desired to have it remain longer in the tissues than is possible with any other.

Fig. 8.—End-to-end suture of the median and ulnar nerves after transposition of the latter and the formation of a fatty bed for the nerves by means of a fat flap: A, the median and ulnar nerves are exposed; the ulnar has been transposed before severing its anatomic continuity in order to prevent axial rotation and prevent distortion of the nerve pattern. B, median and ulnar nerves have been sutured; fat flap has been passed beneath the nerves, covering over the scar tissue bed.

SUTURE MATERIALS

For stay sutures, 00 plain catgut is used. Fine silk offers the best material for grafts and epineural stitches

3. Huber, G. C.: A Study of Operative Treatment for Loss of Nerve Substance in Peripheral Nerves, *J. Morphol.* 2: 1895; Transplantation of Peripheral Nerves, *Arch. Neurol. & Psychiat.* 2: 466 (Oct.) 1919.

in end-to-end suture. The silk should be very fine, preferably Corticelli AAA, which contains three strands. These are untwisted and separated, waxed and passed on fine curved or straight needles. They are boiled at the time of operation and again waxed with sterile wax, after which they are ready for use. Silk thus treated has a certain amount of stiffness and lends itself readily to the delicate tying with forceps so essential to accurate approximation. Further, the silk passes through the small nerve grafts with greater ease and is finer than other forms of silk available. Instead of waxed sutures, arterial silk dipped in liquid petrolatum just before using will be found satisfactory.

All nerve sutures should be tied very carefully with forceps. On the manner of tying and the degree of tension may depend the accurate approximation of the epineurium and the end-to-end apposition of the nerve grafts.

TECHNIC OF END-TO-END SUTURE

A 00 plain catgut suture is passed on each side of the nerve, equidistantly placed, taking a deeper bite than the epineurium. While this suture passes somewhat within the nerve, it really becomes an epineural, perineural and epineurial suture; for, if a smooth needle is used, the funiculi are pushed aside and the suture then lies between the funiculi in the perineural connective tissue and hence does very little harm to the nerve. By these sutures the nerve in its deeper parts is brought together, hemorrhage between the nerve ends is avoided, thereby diminishing the amount of scar between the nerve ends, and tension is taken off the finer epineural sutures.

They may also serve to prevent axial rotation, particularly if they are placed before the excision of the intervening nerve scar is completed. These sutures are tied, leaving the ends about 3 inches long, to which artery forceps are clamped. They then serve to fix the nerve and facilitate in placing the fine epineural sutures.

The silk epineural sutures are then passed on the anterior surface between the two stay sutures. With very fine tooth forceps the *epineurium only* is grasped and each suture accurately placed and then tied with forceps so that the epineural edge is everted. If the sutures have been properly placed, eversion of the epineurium is easily accomplished and gives a smooth line of union on its inner surface. Each suture is cut as it is tied, sufficient sutures being used to insure complete approximation—the number naturally depending on the size of the nerve.

By reversing the two catgut stay sutures, i. e., by passing the one over and the other beneath, the under-surface is readily brought into view and sutured in like manner.

The advantages of the two stay sutures over a single stay are obvious. If a single stay is used, the nerve rotates in remaining sutures, and the nerve is not so easily fixed or its under surface brought into view. If the single stay suture is tied the lateral edges of the nerve become everted, making epineural approximation difficult.

In the presence of a small nerve defect, end-to-end suture may be accomplished by slight stretching, by transposition and by altering the position of the limb. Nerve stretching should be done with considerable caution, since the distance gained can be accomplished only by taking up the normal laxity of the nerve trunk in its contiguous parts, or by multiple tears, either within the nerve trunk or from the spinal cord. When excessive stretching is done, both are accomplished, not only but also, karyolysis of the anterior horn cells ensues, with

subsequent degeneration of the neuraxes within the central stump, an unfortunate result to be studiously avoided.

Stretching should be done only up to the point of taking up the normal laxity of the nerve within its bed.

I have seen two cases in which overstretching was done in a two-stage operation, in which a considerable

Fig. 9.—Technic of nerve transplant: *A*, cutaneous nerve on dorsum of leg is laid bare; the nerve segments are measured and the sutures are passed at precise intervals. *B*, a moist cotton pad about 4 inches square, smoothly folded, is placed over a nerve segment so as to include the sutures; by slight maneuvering with forceps, the sutures and the nerve transplant become adherent to the pad and may be lifted up with the pad; the transplant is not touched. *C*, the cotton pad is shown on which the nerve transplant is lifted together with the sutures, neatly curled, so as to avoid any entanglement; the transplant may then be carried to the operative field without handling and without danger of the threads tearing out, or the graft falling. *D*, the cotton pad is folded back parallel with the nerve segment and placed in the field, carrying the transplant in position for suture; the segment may be flooded off the pad by a small stream of salt solution. *E*, the first segment is shown sutured in place with the second segment ready for suture; after all grafts are in place the stay suture may be removed; it is used merely to facilitate suture of the delicate grafts. *F*, multiple autogenous grafts are shown sutured in place; in this instance the distance bridged was 12 cm.

interval intervened between the first and second operation. The nerve in both instances showed at the second operation marked sclerosis and internal hemorrhage throughout the nerve trunk, with subsequent scar formation as far as the nerve could be palpated. Normal nerve cross areas could not be obtained either central or distal, owing to scar, which was not present at the first operation.

Transposition of the nerve may permit defects to be overcome which might otherwise prevent end-to-end suture. A nerve may be freed and raised out of its bed over quite a distance without interfering with its nutrition. In transposing, care must be taken to safeguard nerve twigs and prevent the formation of sharp angles or kinks.

Huber³ has shown experimentally the value of the multiple autogenous and homogenous grafts, as well as those preserved in alcohol and on ice, in petrolatum and liquid petrolatum. A few cases of successful grafts have been reported in France. The technic of the graft is such that unless done by those having considerable practice it is conceivable that the results may be disappointing. The utmost regard for minute points of technic is essential. Success depends in a measure on the accuracy with which the grafts are brought end on and in precise contact with the cross area of the central and distal stumps. If the sutures are not correctly placed, or if they are not tied properly, just sufficient tension being employed, the nerve ends are likely to be inverted. In place of the graft being end on, it may be turned so that its lateral surface lies against the central cross area. While neuraxes may penetrate, the probability of such penetration is greatly diminished by such faulty approximation. For these reasons, in estimating the ultimate value of the graft, the individual technic must be considered, for it plays a predominating rôle.

A sufficient number of grafts should be taken to cover the cross area of the central and distal stumps. Unless this is done, many central neuraxes, having no path down which they may grow, may become lost, though Huber has shown that a few are able to penetrate and grow down in the small connective tissue spaces between the nerve transplants. The aim of the surgeon should be to connect each funiculus with a graft. This may be accomplished by suturing each graft separately in the desired position. In this manner the central and distal connections may be established with a certain degree of precision. This is often not possible; nevertheless, it should be essayed. For the most accurate surgery, we must await more definite knowledge concerning the internal topography, such as Elsberg⁵ and Riley have signaled they are doing.

TECHNIC OF THE GRAFT

When the nerve is freed from the scar tissue and the nerve ends successively incised until a satisfactory cross area is obtained and before the nerve continuity is completely severed, one or two stay sutures are passed at the proper level, so as to hold the nerve in alignment, prevent rotation, and help in fixation of the nerve ends during suture.

The distance to be bridged is accurately measured with a centimeter compass.

A skin nerve, such as the radial or the cutaneous surae medialis on the dorsum of the leg, may be used.

In order to save time, a second team may lay bare the nerve. Preferably a degenerate nerve should not be used such as one would find in the lower leg on the same side as a sciatic nerve injury. The sheath cells in such a nerve are no longer in the active stage; there may also be some increase in connective tissue, particularly if the injury to the parent nerve is of some standing. It is possible that whatever neurotrophism there may exist would be diminished in such a nerve, as compared with a fresh transplant. However, this is of academic interest rather than of real importance. In view of the downgrowth of neuraxes in preserved specimens, one must question the value of the rôle imputed to neurotrophism.

The nerve having been laid bare over the desired length, fine waxed silk sutures on curved or straight, smooth needles are passed in accordance with the distance to be bridged, as measured with the compass. A small margin is allowed for cutting the nerve segments.

The sutures are all passed in one direction, the nerve being held tense by small forceps either central or distal to the grafts. Under no circumstances should the *nerve segments* to be used in the graft be held by forceps.

The sutures are then curled carefully so as to prevent entanglement; the needles all on one side, and the free ends on the other.

The nerve segments are cut with sharp fine scissors or a thin knife, avoiding crushing the nerve ends.

Each segment is then picked up by covering it with a small, smooth, moist cotton pad. If the cotton pad is carefully placed over the nerve and sutures, they adhere to the moist cotton and each segment may thus be lifted from the wound and placed in the operative field.

By folding the cotton pad so that its free border is parallel to the transplant, the latter may be placed between the nerve ends so as to be in exact position for suture.

By means of the cotton pad the nerve is not handled, the threads do not become entangled, danger of pulling out the suture is eliminated, and the nerve may be manipulated into its proper position for suture with the least trauma. A small stream of salt solution will be found helpful in flooding the nerve off the cotton. During the process of suture, the nerve is irrigated with warm salt, thus creating a clear field and aiding in accurate funicular approximation of the graft. In this manner, each transplant is sutured separately, both distally and centrally, with whichever funiculus is desired. The sutures are tied with forceps and cut short.

The accuracy of the graft depends in a measure on the correct placing of the sutures, the exact amount of tension in tying, and the manipulation with the sutures during the process of tying.

Prevention of Normal Dissipation of Heat as Factor in the Pathology of Children.—A. Czerny expatiates on heat stagnation as an important element in the pathology of older children, the same as it has long been recognized in the case of infants. He states (*Therapie der Gegenwart*, January, 1919), that children used to overcrowding at home do not suffer from the heat stasis in school as much as children used to good hygienic conditions at home. The possibility of heat stasis must be borne in mind not only for well but for sick children as an element in the clinical picture, and the advantages of out-of-door living and sleeping should not be restricted to tuberculous children.

SPECIFIC NATURE OF THE HEMOLYTIC STREPTOCOCCUS OF SCARLET FEVER*

RUTH TUNNICLIFF, M.D.
CHICAGO

On account of the important part that hemolytic streptococci play in scarlet fever and its complications, various observers have undertaken to study the relation of these cocci to scarlet fever by means of immunity experiments.

Moser and von Pirquet¹ concluded that the streptococci from cases of scarlet fever were different from those in other diseases. They found that the serum from scarlet fever patients agglutinated scarlet fever streptococci in low dilutions, the serum from other children but rarely; that normal horse serum agglutinated streptococci from various sources, but only in low dilutions (from 1:4 to 1:64), while the serum of horses immunized with streptococci cultivated from the heart's blood of fatal cases of scarlet fever agglutinated the same streptococci in high dilutions (from 1:1,000 to 1:64,000). The same effects were produced on streptococci cultivated from the heart blood of cases of scarlet fever, which were not used in producing immunity (from 1:1,000 to 1:16,000), while streptococci from other diseases were agglutinated at only a little higher dilution than by normal horse serum (from 1:4 to 1:250), and the serum of horses immunized with the latter streptococci agglutinated streptococci from scarlet fever patients only in the same proportion as normal horse serum.

By means of immune serum, Meyer² differentiated streptococci of angina (scarlatinal, rheumatic, simple) from those of pyogenic infections, but found gradual differences in the reaction of the anginal streptococci which spoke against an identity among them.

The agglutinating action of serum from cases of scarlet fever on scarlatinal streptococci was studied also by Salge.³ He found that those from scarlet fever were agglutinated by scarlatinal serum, but that it caused no agglutination of streptococci from other sources; however, he did not control his work by testing serum from other streptococcus diseases.

After repeating the experiments of Moser and von Pirquet, Aronson⁴ concluded that in no case could he differentiate between streptococcus groups by the most careful agglutination.

Neufeld⁵ also concluded that no specificity of streptococci isolated from scarlet fever could be shown by means of tests with immune rabbit serum.
